(54) Title: **MEMS OPTICAL COMPONENTS**

(57) Abstract: An optical network (100), an optical device, and one or more MEMS optical components (105, 106) are disclosed. The optical network comprises one or more optical input sources (101), one or more optical output collectors (102), and the optical device. The optical device is optically coupled between the one or more optical input sources and the one or more optical output collectors. The optical device is formed on an integrated MEMS chip (104). The optical device comprises the one or more MEMS optical components formed on the integrated MEMS chip. In fact, each MEMS optical component may be monolithically fabricated on, self assemblable on, and reconfigurable or moveable on the integrated MEMS chip.

MEMS OPTICAL COMPONENTS

CROSS REFERENCE TO RELATED APPLICATIONS

This patent application is related to copending PCT Patent Applications Ser. Nos. _____
5 _____ and _____, having respective attorney docket
nos. FP-68000/JAS/SMK and FP-67999/JAS/SMK, with respective titles MEMS
TRANSMISSION AND CIRCUIT COMPONENTS and RECONFIGURABLE QUASI-
OPTICAL UNIT CELLS, and filed on June 9, 2000. These copending applications are
hereby incorporated by reference.

TECHNICAL FIELD OF THE INVENTION

The present invention relates generally to optical networks. In particular, the present
invention pertains to MEMS (micro-electro-mechanical system) optical components that are
integrated together on an integrated MEMS chip to form an optical device used in an optical
network. These MEMS optical components are monolithically fabricated on the chip, self
15 assemblable on the chip, and, in some cases, reconfigurable or moveable on the chip.

BACKGROUND OF THE INVENTION

Optical communication using WDM (wavelength-division-multiplexing) techniques
is a very attractive and economical solution for the bandwidth needs expected for Internet,
video, and multimedia services. The broadband feature of optical communication provides
20 transparency in optical networks where optical signals can carry independent signal formats
without interference. For example, in the same optical fiber at the same time, a first carrier
signal with wavelength λ_1 (i.e., channel 1) could carry analog frequency multiplexed signals,
a second carrier signal with wavelength λ_2 (i.e., channel 2) could carry a 2.5-Gb/s (OC-48)
digital signal, and a third carrier signal with wavelength λ_3 (i.e., channel 3) could carry a

155-Mb/s (OC-3) digital signal. This transparency provides cost reduction, survivability, security, and/or flexibility of the optical networks. Specifically, optical signals can be routed dynamically in or between networks to avoid interruption of services and highly secured or emergency data can reach destinations without interrupting other communication services.

5 Transparency also provides management flexibility to optimize the traffic and bandwidth allocation in optical networks. Furthermore, transparency enables the capacity of optical networks to be greatly increased without significantly increasing costs since existing underground or undersea fiber optic cables can be used.

To achieve such transparency in such optical networks, the optical networks comprise
10 various optical devices, such as WDM multiplexers, switches, filter systems, wavemeters, power regulators, and/or attenuators. These optical devices may themselves comprise optical components, such as gate filters, thin film filters, Fresnel lenses, refractive lenses, grating mirrors, reflective mirrors, and/or tuning plates. However, conventional optical components of the type just described are bulky, cannot be monolithically fabricated, and require manual
15 assembly for proper optical alignment.

In view of the foregoing, there is a need for monolithically fabricated, on-chip assemblable, MEMS optical components. These optical components would be integrated together on an integrated MEMS chip to form an optical device of an optical network.

BRIEF DESCRIPTION OF THE DRAWINGS

20 Fig. 1 shows the configuration of a first embodiment of an optical network that comprises an optical input source, optical output collectors, and a WDM MUX/DMUX optically coupled between the optical input source and the optical output collectors.

Figs. 2, 3, and 4 show the configuration of a MEMS lens/filter optical component of the WDM MUX/DMUX of Fig. 1 in its respective unassembled, partially assembled, and
25 completely assembled states.

Fig. 5 shows the configuration of a element structure of an element structure assembly of the lens/filter optical component of Figs. 2 to 4.

Fig. 6 shows the configuration of a locking latch of each locking latch assembly of the lens/filter optical component of Figs. 2 to 4.

Figs. 7 to 9 show the configuration of each hinge of the element structure assembly of the lens/filter optical component of Figs. 2 to 4.

5 Figs. 10 to 13 show the configuration of two hinges and a support arm of the element structure assembly of the lens/filter optical component of Figs. 2 to 4.

Figs. 14 to 16 show the configuration of the actuator mechanism of the element structure assembly of the lens/filter optical component of Figs. 2 to 4.

10 Fig. 17 shows the configuration of a second embodiment of an optical network that comprises an optical input source, an optical output collector, and a WDM power regulator optically coupled between the optical input source and the optical output collector.

15 Figs. 18, 19, 20, and 21 show the configuration of a MEMS grating mirror optical component of a WDM MUX/DMUX of the WDM power regulator of Fig. 1 in its respective unassembled, first partially assembled, second partially assembled, and completely assembled states.

Fig. 22 shows the configuration of an element structure of an element structure assembly of the grating mirror optical component of Figs. 18 to 21.

Figs. 23 to 25 show the configuration of each hinge of the element structure assembly of the grating mirror optical component of Figs. 18 to 21.

20 Figs. 26 and 27 show the configuration of an additional support arm of the element structure assembly of the grating mirror optical component of Figs. 18 to 21.

Fig. 28 shows the configuration of the rotation hinge of the moveable stage assembly of the grating mirror optical component of Figs. 18 to 21.

25 Figs. 29 and 30 show the configuration of each actuator sub-mechanism of the moveable stage assembly of the grating mirror optical component of Figs. 18 to 21.

Fig. 31 shows the configuration of each gate filter optical component of the WDM MUX/DMUX of the WDM power regulator of Fig. 1 in its unassembled state.

Fig. 32 shows the configuration of each refractive lens optical component of the WDM MUX/DMUX of the WDM power regulator of Fig. 1 in its unassembled state.

Fig. 33 shows the configuration of a refractive lens optical component of an attenuator in an attenuator array of the WDM power regulator of Fig. 1 in its unassembled state.

Fig. 34 shows the configuration of another refractive lens optical component of an attenuator in an attenuator array of the WDM power regulator of Fig. 1 in its unassembled state.

SUMMARY OF THE INVENTION

In summary, the present invention comprises an optical network, an optical device, and one or more MEMS optical components. The optical network comprises one or more optical input sources, one or more optical output collectors, and the optical device. The optical device is optically coupled between the one or more optical input sources and the one or more optical output collectors. The optical device is formed on a integrated MEMS chip that is oriented in a horizontal plane. The optical device comprises the one or more MEMS optical components formed on the chip. In fact, each MEMS optical component may be monolithically fabricated on the chip.

In one embodiment, each MEMS optical component comprises an element structure assembly. The element structure assembly comprises a corresponding actuator mechanism formed on the chip. The corresponding actuator mechanism is configured to be controllably moved laterally with respect to the chip. The element structure assembly also comprises an element structure pivotally coupled to the chip and moveably coupled to the corresponding actuator mechanism. The element structure has a lying position generally parallel to the horizontal plane and an upright position generally perpendicular to the horizontal plane. The element structure comprises an optical element that is configured to optically interact with an input light beam when in the upright position. When the corresponding actuator is controlled to move laterally, the element structure pivots so as to move from the lying position to the upright position so that the optical element can optically interact with the input light beam.

In another embodiment, each MEMS optical component comprises a moveable stage assembly. The moveable stage assembly comprises an actuator mechanism and a moveable stage both formed on the integrated MEMS chip. The actuator mechanism is configured to be controlled to move on the integrated MEMS chip. The moveable stage is fixedly coupled to the actuator mechanism and configured to be moved on the integrated MEMS chip. Each MEMS optical component further comprises an element structure coupled to the moveable stage. The element structure comprises an optical element. When the actuator mechanism is controlled to move, the moveable stage moves the element structure.

DETAILED DESCRIPTION OF THE INVENTION

10 First Exemplary Embodiment

Fig. 1 shows a first exemplary embodiment of the present invention in the form of an optical network 100. The optical network 100 comprises an optical input source 101, N optical output collectors 102-1, 2, 3, 4, ..., N, and a WDM MUX/DMUX (multiplexer/demultiplexer) 103 formed on an integrated MEMS chip 104. The MUX/DMUX 103 is monolithically fabricated on and self assemblable on the chip 104. The MUX/DMUX 103 comprises MEMS filter/lens optical components 105 and 106-1, 2, 3, 4, ..., N that are integrated on the chip 104. The filter/lens optical components 105 and 106-1, 2, 3, 4, ..., N are all monolithically fabricated on the chip 104 and are all self assemblable on the chip 104 under the control of the control circuit 109.

20 The optical input source 101 is configured to provide a collimated input light beam 107-1 having multiple wavelengths $\{\lambda_1, \lambda_2, \lambda_3, \lambda_4, \dots, \lambda_N\}$. The optical input source 101 may comprise an optical fiber, a laser, or other light source.

The MUX/DMUX is used in the optical network 100 for demultiplexing. The optical input source 101 is optically coupled to the MUX/DMUX 103 and provides the MUX/DMUX 103 with the input light beam 107-1. The MUX/DMUX 103 is configured to demultiplex (or separate) the input light beam 107-1 into output light beams 108-1, 2, 3, 4, ..., N having individual wavelengths $\lambda_1, \lambda_2, \lambda_3, \lambda_4, \dots, \lambda_N$, respectively.

The filter/lens optical component 105 is optically coupled to the optical input source 101 to receive the input light beam 107-1. The filter/lens optical component 105 is optically coupled to the first filter/lens optical component 106-1 and is configured to focus and direct the input light beam 107-1 to the first filter/lens optical component 106-1.

5 The filter/lens optical components 106-1, 2, 3, 4, ..., and N-1 are optically coupled to the filter/lens optical components 106-2, 3, 4, ..., N, respectively, to provide the filter/lens optical components 106-2, 3, 4, ..., N with input light beams 107-2, 3, 4, ..., N. The input light beams 107-2, 3, 4, ..., N respectively have the wavelengths $\lambda_2, \lambda_3, \lambda_4, \dots, \lambda_N$, the wavelengths $\lambda_3, \lambda_4, \dots, \lambda_N$, the wavelengths $\lambda_4, \dots, \lambda_N$, ..., the wavelength λ_N . The filter/lens
10 optical components 106-1, 2, 3, 4, ..., N are also optically coupled to the optical output collectors 102-1, 2, 3, 4, ..., N, respectively, to provide the optical output collectors 102-1, 2, 3, 4, ..., N with the output light beams 108-1, 2, 3, 4, ..., N, respectively.

 In performing the functions just described, each filter/lens optical component 106-n, where $n = 1, 2, 3, 4, \dots, N$, is configured to separate a corresponding wavelength λ_n from the
15 wavelengths $\lambda_n, \lambda_{n+1}, \dots, \lambda_N$ of the corresponding input light beam 107-n to produce the corresponding output light beam 108-n. The filter/lens optical component 106-n directs this output light beam 108-n to the corresponding optical output collector 102-n to which the filter/lens optical component 106-n is optically coupled. Each optical output collector 102-n is configured to collect the corresponding output light beam 108-n and may comprise an
20 optical fiber or other light collector.

 Each filter/lens optical component 106-n, where $n = 1, 2, 3, 4, \dots, N-1$, is also configured to reflect the other wavelengths $\lambda_{n+1}, \dots, \lambda_N$ of the corresponding input light beam 107-n to produce the corresponding input light beam 107-n+1 for the next filter/lens optical component 106-n+1. This input light beam 107-n+1 is directed by the filter/lens optical
25 component 106-n to the next filter/lens optical component 106-n+1 to which the filter/lens optical component 106-n is optically coupled.

 The MUX/DMUX 103 also comprises a control circuit 109. The control circuit 109 is integrated on the chip 104 along with the filter/lens optical component 105 and the

filter/lens optical components 106-1, 2, 3, 4, ..., N. However, in an alternative configuration for the MUX/DMUX 103, the control circuit 109 could be located off the chip 104.

5 The MUX/DMUX 103 is self assemblable on the chip 104 under the control of the control circuit 109. This is due to the fact that the filter/lens optical component 105 and the filter/lens optical components 106-1, 2, 3, 4, ..., N are all self assemblable on the chip 104 under the control of the control circuit 109. The filter/lens optical component 105 and the filter/lens optical components 106-1, 2, 3, 4, ..., N are each shown in their completely assembled state in Fig. 1. The self assembly of the filter/lens optical components 105 and 106-1, 2, 3, 4, ..., N provides very accurate automated optical alignment of the filter/lens
10 optical components 105 and 106-1, 2, 3, 4, ..., N on the chip 104. Thus, the effort and the inaccuracy of manual optical alignment on the chip 104 is avoided. The configuration and the self assembly of each of the filter/lens optical components 105 and 106-1, 2, 3, 4, ..., N will be discussed in greater detail next.

Filter/lens optical Component 106-n

15 Figs. 2, 3, and 4 show the configuration of each filter/lens optical component 106-n, where $n = 1, 2, 3, 4, \dots, N$, in its unassembled, partially assembled, and completely assembled states, respectively. Each filter/lens optical component 106-n is monolithically fabricated and comprises an element structure assembly 113 and locking latch assemblies 114. Each filter/lens optical component 106-n also comprises corresponding portions of a
20 semiconductor substrate 110 and an insulating layer 111 of the chip 104 of Fig. 1. The element structure assembly 113 and the locking latch assemblies 114 are formed on this portion of the insulating layer 111.

The element structure assembly 113 comprises an element structure 115. Fig. 2 shows the element structure 115 in a lying position in the unassembled state of the filter/lens
25 optical component 106-n. In this lying position, the element structure 115 is generally parallel to the horizontal plane (and the substrate 110 and the insulating layer 111) in which the chip 104 is oriented. Conversely, Figs. 3 and 4 show the element structure 115 in an upright position in the partially assembled and completely assembled states of the filter/lens

optical component 106-n. In the upright position, the element structure 115 is generally perpendicular to the horizontal plane (and the substrate 110 and the insulating layer 111).

The element structure assembly 113 also comprises corresponding micro-mechanical hinges 116. Each hinge 116 pivotally couples the bottom side of the element structure 115 to the insulating layer 111. This bottom side is parallel to the common rotation axis R_1 of the hinges 116. The top side of the element structure 115 is free and uncoupled. As a result, the element structure 115 can pivot about the rotation axis R_1 of the hinges 116 from its lying position to its upright position. Although the element structure assembly 113 is shown comprising two hinges 116, one or more hinges 116 could be used.

The element structure assembly 113 further comprises corresponding micro-mechanical hinges 117 and 118, a corresponding support arm 119, and a corresponding MEMS actuator mechanism 120. The element structure 115 is moveably coupled to the corresponding actuator mechanism 120 by the hinges 117 and 118 and the support arm 119. More specifically, the hinge 117 pivotally couples a corresponding end of the support arm 119 to the actuator mechanism 120 so that the support arm 119 can pivot about the rotation axis R_2 of the hinge 117. The hinge 118 has a rotation axis R_3 and pivotally couples the corresponding opposite end of the support arm 119 to the left or right side of the element structure 115 that is adjacent to the hinges 117 and 118, the support arm 119, and the actuator mechanism 120. This enables the support arm 119 to also pivot about the rotation axis R_3 of the hinge 118. The rotation axes R_2 and R_3 of the hinges 117 and 118 are parallel to the rotation axis R_1 of the hinge 116. As a result, the hinges 116, 117, and 118 and the support arm 119 cooperatively translate the lateral movement of the actuator mechanism 120 into pivoting movement by the element structure 115 about the rotation axis R_1 .

As mentioned earlier, Fig. 2 shows the filter/lens optical component 106-n in its unassembled state with the element structure 115 in its lying position. To begin assembly of the filter/lens optical component 106-n for normal operation in the MUX/DMUX 103 of Fig. 1, the control circuit 109 of Fig. 1 controls the actuator mechanism 120 of the element structure assembly 113 to laterally move forward. This is done in the manner described later. The hinges 116, 117, and 118 and the support arm 119 cooperatively translate this lateral

forward movement of the actuator mechanism 120 into pivoting movement by the element structure 115 about the rotation axis R_1 until the element structure 115 is in its upright position in the partially assembled state of the filter/lens optical component 106-n shown in Fig. 3. More specifically, when the actuator mechanism 120 moves laterally forward, the
5 corresponding hinge 117 also moves laterally forward so that the end of the corresponding support arm 119 pivotally coupled to the hinge 117 is pushed laterally forward and causes the support arm 119 to pivot about the rotation axis R_2 of the hinge 117. As a result, the opposite end of the support arm 119 pivotally coupled to the corresponding hinge 118 pushes the
10 hinge 118 vertically and rotationally up as the support arm 119 pivots about the rotation axis R_2 of the hinge 118. This in turn causes the hinge 118 to push the element structure 115 vertically and rotationally up so that the element structure 115 pivots about the rotation axis R_1 of the hinges 116 until the element structure 115 is in its upright position.

To properly align the element structure 115 of each filter/lens optical component 106-n in its proper upright position, an optical input source, optical output collectors, and an
15 optical spectrum analyzer may be used. The optical input source would be located so as to direct an input light beam at the element structure 115 in the desired path that the corresponding input light beam 107-n would have in the MUX/DMUX 103. One optical output collector would then be located so as to receive a first output light beam in the desired path that the corresponding output light beam 102-n would have in the MUX/DMUX 103.

20 The other optical output collector would then be located so as to receive a second output light beam in the desired path that the corresponding input light beam 102-n+1 for the next filter/lens optical component 106-n+1 would have in the MUX/DMUX 103. The optical spectrum of the first and second output light beams would then be analyzed with the spectrum analyzer. The pivoting of the element structure 115 would then be controlled until
25 the optical spectrum provided by the spectrum analyzer indicated that the element structure 115 was in the desired upright position. As those skilled in the art will recognize, other methods could also be used to properly align the element structure 115.

Referring again to Figs. 2 to 4, each locking latch assembly 114 comprises a corresponding locking latch (or plate) 121 and a corresponding hinge 116. Figs. 2 and 3

show the locking latch 121 of each locking assembly 114 in a lying position parallel to the insulating layer 111 in the unassembled and partially assembled states of the filter/lens optical component 106-n. On the other hand, Fig. 4 shows the locking latch 121 of each locking latch assembly 114 in a locking position in the completely assembled state of the filter/lens optical component 106-n. In the same way that each hinge 116 of the element structure assembly 113 pivotally couples one side of the element structure 115 to the insulating layer 111, the hinge 116 of each locking latch assembly 114 pivotally couples the bottom side of the corresponding locking latch 121 to the insulating layer 111. This bottom side is parallel to the rotation axis R_4 of the hinge 116. The top side of the locking latch 121 is free and uncoupled in the lying position. The locking latch 121 can therefore pivot about the rotation axis R_4 of the hinge 116 from its lying position to its locking position. The top side of the locking latch 121 includes a slot 122 that is sized to closely receive the corresponding left or right side of the element structure 115 in the locking position.

Similar to the element structure assembly 113, each locking latch assembly 114 also comprises corresponding hinges 117 and 118, a corresponding support arm 119, and a corresponding actuator mechanism 120. The locking latch 121 is moveably coupled to the corresponding actuator mechanism 120 by the hinges 117 and 118 and the support arm 119. This is done in a similar manner to that in which the element structure 115 is moveably coupled to the corresponding actuator mechanism 120 in the element structure assembly 113. Here, however, the hinges 117 and 118 have rotation axes R_5 and R_6 , respectively, so that the support arm 119 pivots about the rotation axes R_5 and R_6 . The rotation axes R_5 and R_6 are parallel to the rotation axis R_4 of the hinge 116. The hinges 116, 117, and 118 and the support arm 119 therefore cooperatively translate the lateral movement of the actuator mechanism 120 into pivoting movement by the locking latch 121 about the rotation axis R_4 .

In the unassembled and partially assembled states of the filter/lens optical component 106-n shown in Figs. 2 and 3, the locking latch 121 of each locking latch assembly 114 is in its lying position. To place the filter/lens optical component 106-n in the completely assembled state after the element structure 115 is in the upright position of the partially assembled state shown in Fig. 3, the control circuit 109 of Fig. 1 controls the actuator

mechanism 120 of the element structure assembly 113 to laterally move forward so that the hinges 116, 117, and 118 and the support arm 119 cooperatively translate this lateral forward movement into pivoting movement by the locking latch 121 about the rotation axis R_4 . The locking latch 121 is pivoted about the rotation axis R_4 until the locking latch 121 is in its locking position in the completely assembled state of the filter/lens optical component 106-n shown in Fig. 4. The manner in which this is done is similar to that in which the control circuit 109 causes the element structure 115 of the element structure assembly 113 to be pivoted until it is in its upright position. Here, however, the pivoting of the support arm 119 of each locking latch assembly 114 occurs about the rotation axes R_5 and R_6 and the pivoting of the locking latch 121 of each locking latch assembly 114 occurs about the rotation axis R_4 .

However, it may be the case that the element structure 115 of each filter/lens optical component 106-n is stable enough for proper optical alignment in its upright position with only one or even no locking latch assemblies 114. Thus, each filter/lens optical component 106-n could comprise none or one or more locking latch assemblies 114.

Furthermore, as those skilled in the art will recognize, each filter/lens optical component 106-n is also disassemblable. In order to disassemble each filter/lens optical component 106-n, the reverse process to the assembly process just described would be used. However, in some applications it may be the case that only assembly is required.

Filter Pate Assembly 113

Fig. 5 shows the configuration of the element structure 115 of the element structure assembly 113 of Figs. 2 to 4. The element structure 115 comprises a support plate 127, a thin film bandpass filter optical element 123 formed on the support plate 127, and a planar Fresnel lens optical element 124 formed on/in the support plate 127.

The bandpass filter optical element 123 is configured to optically interact with the corresponding input light beam 107-n to allow a corresponding wavelength λ_n of the wavelengths $\lambda_n, \lambda_{n+1}, \dots, \lambda_N$ in the corresponding input light beam 107-n of Fig. 3 to pass through the bandpass filter optical element 123 while reflecting the other wavelengths $\lambda_{n+1}, \dots, \lambda_N$. The bandpass filter optical element 123 comprises alternating high and low

reflectivity thin film material plates 125 and 126 formed on one side of the support plate 127. The thin film material plates 125 and 126 are spaced at quarter wavelengths from each other.

The Fresnel lens optical element 124 is configured to optically interact with the corresponding input light beam 107-n by focusing and directing the corresponding wavelength λ_n passed by the bandpass filter optical element 123 to produce the output light beam 108-n of Fig. 3. The Fresnel lens optical element 124 comprises a Fresnel pattern 128 formed on the opposite side of the support plate 127 on which the thin film material plates 125 and 126 are formed. The Fresnel pattern 128 may be integrally formed with the support plate 127 by appropriately etching the support plate 127 to produce the Fresnel pattern 128. Alternatively, a metal pattern could be formed on the support plate 127 to produce the Fresnel lens optical element 124.

Figs. 7 to 9 show the configuration of each hinge 116 of the element structure assembly 113 of Figs. 2 to 4. Each hinge 116 comprises a first hinge plate 130, a hinge pin 131, a locking arm 132, a second hinge plate 133, anchors 134, vias 148, and a base 138. The base 138 is fixedly coupled to the insulating layer 111. The hinge plate 130 is fixedly coupled to the base 138 with anchors 134. The hinge pin 131 is disposed and rotates in an opening 135 of the hinge plate 130 along the rotation axis R_1 of the hinge 116. The locking arm 132 is fixedly coupled to the hinge plate 130 with vias 148 and extends over the opening 135. The opposite ends of the hinge pin 131 include attachment arms 136 while the hinge plate 133 also includes attachment arms 137. Each attachment arm 136 is fixedly coupled to a corresponding attachment arm 137 with a corresponding via 148. The end of each attachment arm 137 extends over the hinge plate 130. This enables the locking arm 132 and the attachment arms 137 to cooperatively rotatably lock the hinge pin 131 in place so that the hinge pin 131 can rotate about the rotation axis R_1 . As a result, the hinge plate 133 can correspondingly pivot about the rotation axis R_1 .

The hinge plate 133 is fixedly coupled to the bottom side of the element structure 115. In fact, the hinge plate 133 may be integrally formed with the bottom side of the support plate 127 of the element structure 115. When the hinge plate 133 pivots about the rotation axis R_1 , the element structure 115 does the same.

Figs. 10 to 13 also show the configuration of each support arm 119 of the element structure assembly 113 of Figs. 2 to 4. Each support arm comprises a corresponding first support strip 152, a corresponding second support strip 153, and a corresponding via 148. The first and second support strips 152 and 153 are fixedly coupled to each other by the via 148.

Figs. 10 to 13 further show the configuration of each hinge 117 of the element structure assembly 113 of Figs. 2 to 4. The hinge 117 is configured and operates similar to the hinge 116 of Figs. 7 to 9 in that it comprises a first hinge plate 130, a hinge pin 131 with attachment arms 136, a locking arm 132, a second hinge plate 133 with attachment arms 137, and vias 148. However, in contrast to each hinge 116, the hinge 117 comprises a guide plate 139 that is stationary and fixedly coupled to the insulating layer 111 and the hinge plate 130 laterally slides on the guide plate 139. The hinge 117 also comprises guiding overhangs 140 and anchors 154 for the guiding overhangs 140.

Each guiding overhang 140 is fixedly coupled to the guide plate 139 by a corresponding anchor 154. Each anchor 154 extends up from the guide plate 139 along the outer surface of the hinge plate 130 and the guiding overhang extends over the upper surface of the hinge plate 130. Together, these guiding overhangs 140 guide the hinge plate 130 as it moves laterally on the guide plate 139.

In the case of the hinge 117, the hinge plate 130 also comprises contact rails 149 to enable the hinge plate 130 to laterally slide on the guide plate 139 with minimal friction and stiction. Each rail 149 may be continuous or may comprise a row of protrusions or bumps.

As in the hinge 116 of Figs. 7 to 9, the locking arm 132 and the attachment arms 137 of the hinge plate 133 of the hinge 117 cooperatively rotatably lock the hinge pin 131 in place within the opening 135 of the hinge plate 130. As a result, the hinge pin 131 can rotate about the rotation axis R_2 of the hinge 117 and the hinge plate 133 can correspondingly pivot about the rotation axis R_2 .

In the element structure assembly 113 of Figs. 2 to 4, the hinge plate 130 of the hinge 117 is fixedly coupled to an insulating attachment bridge 141 of the corresponding actuator mechanism 120 of the element structure assembly 113. As a result, the hinge plate 130

moves laterally with the actuator when the actuator mechanism 120 is controlled to move laterally by the control circuit 109 of Fig. 1. The hinge plate 133 is fixedly coupled to one end of the support arm 119 and in fact may be integrally formed with the support strip 152 of the support arm 119 at that end. The support arm 119 is therefore pivotally coupled to the actuator mechanism 120 by the hinge 117 so that the support arm 119 can pivot about the rotation axis R_2 of the hinge 117 when the actuator mechanism 120 is controlled to move laterally.

Figs. 10 to 13 also show the configuration of each hinge 118 of the element structure assembly 113 of Figs. 2 to 4. Like the hinge 117, the hinge 118 is also configured and operates similar to the hinge 116 of Figs. 7 to 9 in that it also comprises a first hinge plate 130, a hinge pin 131 with attachment arms 136, a locking arm 132, a second hinge plate 133 with attachment arms 137, and vias 148. However, the configuration of the hinge 118 is upside down from that of the hinges 116 and 117 and both the hinge plates 130 and 133 pivot about the rotation axis R_3 in the case of the hinge 118 in the element structure assembly 113 or the rotation axis R_6 in the case of the hinge 118 in each locking latch assembly 114. As in the hinges 116 and 117, the locking arm 132 and the attachment arms 137 of the hinge plate 133 cooperatively rotatably lock the hinge pin 131 in place within the opening 135 of the hinge plate 130. In the case of the hinge 118 in the element structure assembly 113, this enables the hinge pin 131 to rotate about the rotation axis R_3 and both hinge plates 130 and 133 to correspondingly pivot about the rotation axis R_3 . The same is true for the hinge 118 in each locking latch assembly 114 except that the hinge pin 131 rotates and the hinge plates 130 and 133 pivot about the rotation axis R_6 .

In the element structure assembly 113 of Figs. 2 to 4, the hinge plate 130 of the hinge 118 is fixedly coupled to the left or right side of the element structure 115 that is adjacent to the hinges 117 and 118, the support arm 119, and the actuator mechanism 120 of the element structure assembly 113. In fact, the hinge plate 130 may be integrally formed with the support plate 127 of Fig. 5 of the element structure 115 at this side. This is done in a similar manner to that in which the hinge plate 133 of the hinge 116 of Figs. 7 to 9 is integrally formed with the support plate 127. Furthermore, referring back to Figs. 10 to 13, the hinge

plate 133 of the hinge 118 is fixedly coupled to the opposite end of the support arm 119 to that which the hinge plate 133 is fixedly coupled. The hinge plate 133 may be integrally formed with the support strip 153 of the support arm 119 at that end. As a result, the support arm 119 is also pivotally coupled to the element structure 115 by the hinge 118 so that the support arm 119 can also pivot about the rotation axis R_3 of the hinge 118.

Figs. 14 to 16 show the configuration of each actuator mechanism 120 of the element structure assembly 113 of Figs. 2 to 4. The actuator mechanism 120 comprises actuator sub-mechanisms 142 and the insulating attachment bridge 141 mentioned earlier. One of the actuator sub-mechanisms 142 is configured for forward movement and the other is configured for backward movement. Each actuator sub-mechanism 142 comprises a conductive support frame 143 that is fixedly coupled to the support frame 143 of the other actuator sub-mechanism 142 with the insulating attachment bridge 141. The insulating attachment bridge 141 fixedly couples, but electrically isolates, the support frames 143 of the actuator sub-mechanisms 142.

Each actuator sub-mechanism 142 also comprises an array of SDAs (scratch-drive actuators) 144 and conductive flexible attachment arms 145. Each SDA 144 is fixedly coupled and electrically connected to the support frame 143 of the actuator sub-mechanism 142 by corresponding attachment arms 145.

As shown in Figs. 15 and 16, each SDA 144 comprises a corresponding plate 146 and a corresponding bushing 147. The plate 146 is fixedly coupled and electrically connected to corresponding attachment arms 145 and may be integrally formed with these attachment arms 145. The attachment arms 145 are themselves fixedly coupled and electrically connected to the support frame 143 of the corresponding actuator sub-mechanism 142 by vias 148 of the actuator sub-mechanism 142.

Referring back to Fig. 14, the SDAs 144 of each actuator sub-mechanism 142 are aligned for forward or backward movement depending on whether the actuator sub-mechanism 142 is to be used for forward or backward movement. The SDAs 144 are of the type described in T. Akiyama and K. Shono, "Controlled Stepwise Motion in Polysilicon Microstructures", J. of MEMS, Vol. 2, No. 3, pp. 106, Sept. 1993, and T. Akiyama and H.

Fujita, "A Quantative Analysis of Scratch Drive Actuator Using Buckling Motion", IEEE Micro Electro Mechanical Networks, pp. 310-315, 1995. These articles are hereby incorporated by reference.

Referring again to Figs. 15 and 16, each actuator sub-mechanism 142 also comprises
5 conductive contact rails 149 and conductive bias lines 150. The contact rails 149 are fixedly coupled to and patterned on the lower surface of the support frame 143 of the actuator sub-mechanism 142 and, in fact, may be integrally formed with the support frame 143. The contact rails 149 are also electrically connected to the support frame 143. The bias lines 150 are fixedly coupled to and patterned on the insulating layer 111. The contact rails 149
10 laterally slide on and electrically contact the bias lines 150. Thus, the contact rails 149 enable the support frame 143 to laterally slide on and be electrically connected to the bias lines 150 with minimal friction and stiction. Each contact rail 149 may be continuous or may comprise a row of protrusions or bumps.

Turning now to Figs. 14 to 16, the conductive plate 146 of each SDA 144 of each
15 actuator sub-mechanism 142 is electrically connected to the bias lines 150 of the actuator sub-mechanism 142 with the contact rails 149, the support frame 143, and the attachment arms 145 of the actuator sub-mechanism 142. Thus, when a periodic square wave bias signal is applied to the bias lines 150 by the control circuit 109 109 of Fig. 1, this signal is provided to the plate 146. Since the semiconductor substrate 110 is grounded, this causes the plate 146
20 to be pulled down toward the insulating layer 111 each time the signal reaches a high voltage. The plate 146 is pulled down because of the flexure in the flexible conductive attachment arms 145. Each time this occurs, the bushing 147 of the SDA 144 reaches out and contacts the insulating layer 110. Then, each time the signal goes to a low voltage, the plate 146 returns to its original position and the bushing 147 pulls the actuator mechanism 120 forward
25 or backward a step depending on whether the actuator sub-mechanism 142 is configured for forward or backward movement. In this way, the SDAs 144 of the actuator sub-mechanism 142 configured for forward movement collectively move the entire actuator mechanism 120 forward in stepwise fashion and the SDAs configured for backward movement collectively move the entire actuator mechanism 120 backward in stepwise fashion.

Referring back to Fig. 14, each actuator mechanism 120 also comprises guiding overhangs 140 that are configured and operate like those of the hinge 117 of Figs. 10 to 13. As shown in Fig. 15, each guiding overhang 140 is fixedly coupled to a corresponding bias line 150 by an anchor 154 of the actuator mechanism 120. Each anchor 154 extends up from the corresponding bias line 150 along the outer surface of the support frame 143 and the guiding overhang 140 extends over the upper surface of the support frame 143 of the corresponding actuator sub-mechanism 142. Referring again to Fig. 14, the guiding overhangs 140 collectively guide the entire actuator mechanism 120 as it moves forward or backward.

In an alternative configuration, each actuator mechanism 120 could comprise an array of side-drive actuators, such as those described in L. Fan, Y.C. Tai, and R. Muller, "IC Processed Electrostatic Micromotors", *Sensors and Actuators*, Vol. 20, pp. 41-47, Nov. 1989. Or, each actuator mechanism 120 could comprise an array of comb-drive actuators, such as those described in W. Tang, T. Nguyen, and R. Howe, "Laterally Driven Polysilicon Resonant Microstructures", *Sensors and Actuators*, Vol. 20, pp. 25, Nov. 1989. Both of these articles are hereby incorporated by reference. Additionally, thermal actuators, piezoelectric actuators, and electromagnetic actuators or other types of actuators could also be used.

Locking Pate Assembly 114

Fig. 6 shows the configuration of the locking latch 121 of each locking latch assembly 114 of the filter/lens optical component 106-n of Figs. 2 to 4. The locking latch 121 has a slot 122 at its top side. As mentioned previously, the slot 122 is sized to closely receive the corresponding left or right side of the element structure 115 in the locking position of the locking latch 121.

The configuration of each hinge 116 of each locking latch assembly of Figs. 2 to 4 is the same as that shown in Figs. 7 to 9 except that the hinge plate 133 is fixedly coupled to the bottom side of the locking latch 121. In fact, it may be integrally formed there with the bottom side of the locking latch 121. Furthermore, pivoting of the hinge plate 133 and the locking latch 121 and rotation of the hinge pin 131 occurs about the rotation axis R_4 .

Similarly, the configuration and operation of the hinge 117 and the support arm 119 of each locking latch assembly of Figs. 2 to 4 is the same as that shown in Figs. 10 to 13 except for a few differences. The rotation of the hinge pin 131 and the pivoting of the hinge plate 133 and the support arm 119 occurs about the rotation axis R_5 . Furthermore, in the locking latch assembly 114 of Figs. 2 to 4, the hinge plate 130 of the hinge 117 is fixedly coupled to an insulating attachment bridge 141 of the corresponding actuator mechanism 120 of the locking latch assembly 114. The configuration of the actuator mechanism 120 of each locking latch assembly of Figs. 2 to 4 is the same as that shown in Figs. 14 to 16.

Finally, the configuration of the hinge 118 of each locking latch assembly of Figs. 2 to 4 is also the same as that shown in Figs. 10 to 13 except for a few differences. Specifically, the pivoting of the hinge plates 130 and 133 and the support arm 119 and the rotation of the hinge pin 131 occurs about the rotation axis R_6 . In addition, the hinge plate 130 is fixedly coupled to the left or right side of the locking latch 121 that is adjacent to the hinges 117 and 118, the support arm 119, and the actuator mechanism 120 of the locking latch assembly 114. The hinge plate 130 may be integrally formed with the locking latch 121 at this side.

Alternative Configurations

Referring again to Fig. 1, the self assembly of each filter/lens optical component 106-n just described provides very accurate automated optical alignment of the filter/lens optical component 106-n on the chip 104. Thus, the effort and the inaccuracy of manual optical alignment on the chip 104 is avoided.

However, as those skilled in the art will recognize, each filter/lens optical component 106-n could be configured, operate, and be self assemblable similar to the refractive lens optical component 256-m in Fig. 33 for each attenuator 255-m of Fig. 17. In this case, the filter/lens optical component 106-n could comprise a moveable stage assembly 260.

Furthermore, the element structure assembly 113 would be replaced by an element structure assembly that is configured and operates like the refractive lens plate assembly 261 of the refractive lens optical component 256-m, except that the element structure 115 would replace the refractive lens plate 264. Finally, the locking latch assemblies 114 would be replaced by

one or more locking latch assemblies 221. In this case, the optical alignment of the filter/lens optical component 106-n could be made even more precise by laterally moving the moveable stage 262 to adjust the position of the element structure 115 of Figs. 2 to 4.

Filter/lens optical Component 105

5 Referring again to Fig. 1, the filter/lens optical component 105 is configured, operates, and is self assemblable on the chip 104 under the control of the control circuit 109 in a similar manner as that just described for each filter/lens optical component 106-n. Thus, except for the differences mentioned next, the foregoing discussion of each filter/lens optical component 106-n is also applicable to the filter/lens optical component 105.

10 The filter/lens optical component 105 comprises an element structure 115 like that shown in Fig. 5 for each filter/lens optical component 106-n. The element structure 115 comprises a Fresnel lens optical element 124 like that of each filter/lens optical component 106-n shown in Fig. 5. Referring to Fig. 1, this Fresnel lens directs the input light beam 107-1 to the first filter/lens optical component 106-1. Turning to Fig. 5 again, the filter/lens
15 optical component 105 may also comprises a bandpass filter optical element 123 similar to that of each filter/lens optical component 106-n. Referring back to Fig. 1, this bandpass filter optical element 123 however would be configured to pass all of the wavelengths $\lambda_1, \lambda_2, \lambda_3, \lambda_4, \dots, \lambda_N$ being multiplexed by the MUX/DMUX 103 so that the input light beam 107-1 includes them all but excludes other wavelengths.

20 Furthermore, the alignment of the element structure 115 of the filter/lens optical component 105 would be similar to that described earlier for each filter/lens optical component 106-n except that only one optical output collector would be needed. This optical output collector would be located so as to receive an output light beam in the desired path that the input light beam 107-1 would have in the MUX/DMUX 103.

Fabrication Process

The MUX/DMUX 103 may be fabricated using a three polysilicon layer process. This of course also means that the filter/lens optical component 105 and the filter/lens optical components 106-1 to N may each be formed with this same three polysilicon layer process.

Referring to Figs. 5 to 16, in this process, the insulating layer 111 (insulating 0) is first deposited on the substrate 110. The substrate may comprise silicon and the insulating layer may comprise silicon nitride.

Then, a first polysilicon layer (poly 0) is deposited on the insulating layer 111. This polysilicon layer is selectively patterned on the insulating layer 111 to form the base 138 in Figs. 8 and 9 of each hinge 116, the guide plate 139 in Figs. 10 to 13 of each hinge 117, and the bias lines 150 in Figs. 14 and 15 of each actuator mechanisms 120.

A first sacrificial layer, such as a PSG (phosphorous silicate glass) like silicon dioxide, is then deposited on the insulating layer 111 and the patterned first polysilicon layer. This sacrificial layer is then selectively etched down to the base 138 of each hinge 116 to form openings for the anchors 134 in Figs 8 and 9 (anchor 1) of each hinge 116 and down to the guide plate 139 of each hinge 117 and the bias lines 150 of each actuator mechanism 120 to form openings for the anchors 154 of Figs. 13 and 15 (anchor 2) of each hinge 117 and each actuator mechanism 120. This sacrificial layer is also selectively etched to form dimples in it for the formation of the contact rails 149 in Fig. 14 of each support frame 143 and the contact rails 149 in Fig. 13 of each hinge plate 130.

A second polysilicon layer (poly 1) is then deposited on the first sacrificial layer and in the openings just mentioned. This polysilicon layer is then selectively patterned to form the hinge plate 130 and the hinge pin 131 in Figs. 7 to 9 of each hinge 116, the hinge plate 130, the contact rails 149, and the hinge pin 131 in Figs. 10 to 13 of each hinge 117, the support strip 153 in Figs. 10 to 12 of each support arm 119, the hinge plate 133 and the locking arm 132 in Figs. 10 and 12 of each hinge 118, the support frame 143 and the contact rails 149 in Figs. 14 to 16 of each actuator mechanism 120, the anchors 134 in Figs. 8 and 9 of each hinge 116, and the lower portions of the anchors 154 of Figs. 13 and 15 of each hinge 117 and each actuator mechanism 120.

A second insulating layer (insulating 1) is then deposited on the first sacrificial layer and the patterned second polysilicon layer. Like the first insulating layer 111 (insulating 0), this insulating layer may comprise silicon nitride. The second insulating layer is then selectively patterned to form the insulating attachment bridge 141 in Figs. 14 and 15 of each actuator mechanisms 120.

A second sacrificial layer that is of the same material as the first sacrificial layer is then deposited on the first sacrificial layer, the patterned second polysilicon layer, and the patterned second insulating layer. The second sacrificial layer is selectively etched down to the lower portions of the anchors 154 in Figs. 13 and 15 of each hinge 117 and each actuator mechanism 120 to provide openings for the upper portions of these anchors 154. The second sacrificial layer is also selectively etched down to the hinge plate 130 and the hinge pin 131 in Figs. 8 and 9 of each hinge 116, the hinge plate 130 and the hinge pin 131 in Figs. 11 and 12 of each hinge 117, the support strip 153 in Figs. 11 and 12 of each support arm 119, the hinge plate 133 and the locking arm 132 in Figs. 11 and 12 of each hinge 118, and the support frame 143 in Fig. 15 of each actuator mechanism 120 to provide openings for the formation of the corresponding vias 148 in Figs. 8, 9, 11, 12, and 15 of each hinge 116, 117, and 118, each support arm 119, and each actuator mechanism 120. The second sacrificial layer is further selectively etched to form dimples in the second sacrificial layer for the formation of the bushing 147 in Figs. 9 and 10 of each SDA 144.

A third polysilicon layer (poly 2) is then deposited on the second sacrificial layer and in the openings just mentioned. This polysilicon layer is then selectively patterned to form the upper portions of the anchors 154 just mentioned, the vias 148 just mentioned, the hinge plate 133 and locking arm 132 in Figs. 7 to 9 of each hinge 116, the support plate 127 in Figs. 5, 8, and 9 including the Fresnel pattern 128 in Fig. 5 of each element structure 115, each locking latch 121 including the corresponding slot 122 in Fig. 6, the hinge plate 133 and locking arm 132 in Figs. 10 to 12 of each hinge 117, the hinge plate 130 and hinge pin 131 in Figs. 10 to 12 of each hinge 118, the support strip 152 in Figs. 10 to 12 of each support arm 119, the guiding overhangs 140 in Figs. 13 and 14 of each hinge 117 and each actuator

mechanism 120, the SDAs 144 including the bushings 147 in Figs. 15 and 16 of each actuator mechanism 120.

A third sacrificial layer is then deposited on the second sacrificial layer and the patterned third polysilicon layer. This third sacrificial layer is of the same material as the first and second sacrificial layers. This sacrificial layer is then selectively etched down to the support plate 127 in Fig. 5 of each element structure 115 to form an opening over the support plate 127 while the gaps in the support plate 127 caused by the Fresnel pattern 128 are still filled with the sacrificial layer.

Then, alternating layers of high and low reflectivity thin film materials are deposited on the third sacrificial layer and in the opening over the support plate 127 in Fig. 5 of each element structure 115. These thin film layers are then selectively patterned to form the thin film material plates 125 and 126 on the support plate 127 of each element structure 115.

Finally, the first, second, and third sacrificial layers are removed. This frees all of the hinges 116, 117, and 118, the element structures 115, the locking latches 121, and the actuator mechanisms 120 in Figs. 2 to 4 for movement in the manner described earlier.

Alternative Embodiments

In Fig. 1, the MUX/DMUX 103 is used in the optical network 100 for demultiplexing. However, those skilled in the art will recognize that the MUX/DMUX 103 could also be used for multiplexing. In this case, the configuration and operation of the optical network 100 would be the reciprocal of that just discussed.

Second Exemplary Embodiment

Fig. 17 shows a second exemplary embodiment of the present invention, namely another optical network 200. The optical network 200 comprises an optical input source 201, and optical output collector 202, and a WDM power regulator (i.e., equalizer) 203 implemented on the integrated MEMS chip 104.

The optical input source 201 is configured to transmit an input light beam 205 having multiple wavelengths λ_1 to λ_M , where $M \geq 2$. The optical input source 201 may comprise an optical fiber, a laser, or other light source.

5 The WDM power regulator 203 is optically coupled to the optical input source 201 to receive the input light beam 205. The WDM power regulator 203 is monolithically fabricated on the chip 104 and is self assemblable on and reconfigurable on the chip 104 under the control of the control circuit 109. The WDM power regulator is configured to separately regulate the respective power levels of the wavelengths λ_1 to λ_M of the input light beam 205. This produces an output light beam 206 with the wavelengths λ_1 to λ_M at respective
10 regulated power levels.

The optical output collector 202 is optically coupled to the WDM power regulator 203 to receive the output light beam 206. The optical output collector 202 is configured to transmit the output light beam 206 and may comprise an optical fiber or other light collector.

15 In order to perform the power regulation just described, the WDM power regulator 203 comprises MEMS MUX/DMUXs 207-1 and 207-2 and a MEMS attenuator array 208 that are all integrated on the chip 104. In fact, the MUX/DMUXs 207-1 and 207-2 and the attenuator array 208 are all monolithically fabricated on the chip 104 and are all self assemblable on and reconfigurable on the chip 104 under the control of the control circuit 109.

20 The MUX/DMUX 207-1 is optically coupled to the optical input source 201 to receive the input light beam 205. The MUX/DMUX 207-1 is configured on the chip 104 to demultiplex the input light beam 205 into individual light beams 210-1 to M with respective wavelengths λ_1 to λ_M .

25 The attenuator array 208 is optically coupled to the MUX/DMUX 207-1 to receive the individual light beams 210-1 to M. The attenuator array 208 is configured to separately regulate the power levels of the individual light beams 210-1 to M by separately attenuating them. This produces the separately regulated light beams 211-1 to M with respective wavelengths λ_1 to λ_M and respective regulated power levels.

The MUX/DMUX 207-2 is optically coupled to the attenuator array 208 to receive the separately regulated light beams 211-1 to M. The MUX/DMUX 207-2 is configured on the chip 104 to multiplex the separately regulated light beams 211-1 to M into the single output light beam 206 comprising the wavelengths λ_1 to λ_M at respective regulated power levels.

5 The optical output collector 202 is optically coupled to the MUX/DMUX 207-2 to receive the output light beam 206.

The WDM power regulator 203 also comprises a control circuit 109. The control circuit 109 is integrated on the chip 104 along with the MUX/DMUXs 207-1 and 207-2 and the attenuator array 208. However, in an alternative configuration for the WDM power
10 regulator 203, the control circuit 109 could be located off the chip 104. The MUX/DMUXs 207-1 and 207-2 and the attenuator array 208 are each self assemblable on and reconfigurable on the chip 104 under the control of the control circuit 109. Thus, the entire WDM power regulator 203 is itself self assemblable on and reconfigurable on the chip 104 under the control of the control circuit 109.

15 MUX/DMUX 207-1

Still referring to Fig. 17, the MUX/DMUX 207-1 comprises a MEMS grating mirror optical component 215, a MEMS gate filter array 216, and a MEMS refractive lens array 217. The grating mirror optical component 215, the gate filter array 216, and the refractive lens array 217 are all monolithically fabricated on the chip 104 and are all self assemblable on the
20 chip 104 under the control of the control circuit 109.

In its completely assembled state, the grating mirror optical component 215 is optically coupled to the optical input source 201 to receive the input light beam 205. The grating mirror optical component 215 is reconfigurable on the chip 104 under the control of the control circuit 109. This is due to the fact that the grating mirror optical component 215
25 is configured to be rotated to a selected position to spread the input light beam 205 out into its spectrum of wavelengths at different angles to produce a wide spectrum light beam 209 with these wavelengths at the different angles. These wavelengths of course include the wavelengths λ_1 to λ_M .

The gate filter array 216 comprises MEMS gate filter optical components 218-1 to M for passing only the wavelengths λ_1 to λ_M of the wide spectrum light beam 209 to produce the filtered light beams 213-1 to M with the respective wavelengths λ_1 to λ_M . The gate filter optical components 218-1 to M are all monolithically fabricated on the chip 104 and are all self assemblable on the chip 104 under the control of the control circuit 109. In its completely assembled state, each gate filter optical component 218-m, where $m = 1$ to M, is configured to pass a corresponding wavelength λ_m at a corresponding angle from among the other wavelengths of the wide spectrum light beam 209 that are around the wavelength λ_m . This results in a corresponding filtered light beam 213-m with the corresponding wavelength λ_m at a corresponding angle.

The refractive lens array 217 comprises MEMS refractive lens optical components 219-1 to M for re-focusing the filtered light beams 213-1 to M to produce the individual light beams 210-1 to M with the respective wavelengths λ_1 to λ_M . The refractive lens optical components 219-1 to M are all monolithically fabricated on the chip 104 and are all self assemblable on the chip 104 under the control of the control circuit 109. In its completely assembled state, each refractive lens optical component 219-m is configured to re-focus a corresponding filtered light beam 213-m to produce the corresponding individual light beam 210-n with the wavelength λ_m .

Optical Grating Mirror Component 215

Figs. 18, 19, 20, and 21 show the configuration of the grating mirror optical component 215 in its unassembled, first partially assembled, second partially assembled, and completely assembled states, respectively. Similar to each filter/lens optical component 106-n of Figs. 2, 3, and 4, the grating mirror optical component 215 is monolithically fabricated on the chip 104 and self assemblable on the chip 104 under the control of the control circuit 109.

Like the lens/filter optical component 106-n of Figs. 2 to 4, the grating mirror optical component 215 comprises an element structure assembly 113 and a locking latch assembly 114. However, the grating mirror optical component 215 also comprises a moveable stage

assembly 222. The grating mirror optical component 215 further comprises corresponding portions of a semiconductor substrate 110 and an insulating layer 111 of the chip 104 of Fig. 16. The element structure assembly 113, the locking latch assembly 114, and moveable stage assembly 222 are formed on this portion of the insulating layer 111.

5 The moveable stage assembly 222 comprises a moveable stage 225, a micro-mechanical rotation hinge 226, and an actuator mechanism 120. The moveable stage 225 is configured so that it can be rotatably moved by the actuator mechanism 120. Specifically, the moveable stage 225 is rotatably coupled to the insulating layer 111 by the rotation hinge 226 so that it can rotate about the rotation axis R_7 of the rotation hinge 226 when the grating
10 mirror optical component 215 is in its completely assembled state. The actuator mechanism 120 is fixedly coupled to the moveable stage 225 and can be controlled by the control circuit 109 of Fig. 17 to move along an arc so as to cause the moveable stage 225 to rotate about the rotation axis R_7 when the grating mirror optical component 215 is in its completely assembled state.

15 With respect to on-chip assembly of the grating mirror optical component 215, the element structure assembly 113 is configured and operates similar to the element structure assembly 113 of the filter/lens optical component 106-n of Figs. 2 to 4 except for the differences discussed next. The element structure assembly 113 here comprises micro-mechanical hinges 229 instead of the hinges 116 and comprises an additional support arm
20 230. The element structure 115 is pivotally coupled to the moveable stage 225 of the moveable stage assembly 222 by the hinges 229. Here, the support arm 230 is pivotally coupled to the support arm 119 by the hinge 118. A portion of the support arm 230 extends underneath and supports the left or right side of the element structure 115 that is adjacent to the hinges 117 and 118, the support arm 119, and the actuator mechanism 120 of the element
25 structure assembly 113 without being physically coupled to the element structure 115. Thus, the hinges 229, 117, and 118 and the support arms 119 and 230 cooperatively translate the forward lateral movement of the actuator mechanism 120 into pivoting movement by the element structure about the rotation axis R_1 of the hinges 229. This is done under the control of the control circuit 109 of Fig. 17 until the element structure 115 has been moved from its

lying position in Fig. 18 in the unassembled state of the grating mirror optical component 215 to its upright position in Fig. 19 in the first partially assembled state of the grating mirror optical component 215. Although the element structure assembly 113 is shown comprising two hinges 229, those skilled in the art will recognize that one or more hinges 229 could be used.

Proper alignment of the element structure 115 in its upright position is done in a similar manner to that described earlier for the element structure 115 of each filter/lens optical component 106-n. An optical input source is located so as to direct an input light beam at the element structure 115 in the desired path that the input light beam 205 would have in the MUX/DMUX 207-1. Furthermore, an optical output collector would then be located so as to receive a wide spectrum output light beam in the desired path that the wide spectrum light beam 209 would have in the MUX/DMUX 207-1. The optical spectrum of the output light beam would then be analyzed with a spectrum analyzer. The pivoting of the element structure 115 would then be controlled until the optical spectrum provided by the spectrum analyzer indicated that the element structure 115 was in the desired upright position. As those skilled in the art will recognize, other methods could also be used to properly align the element structure 115.

Referring again to Figs. 18 to 21, the locking latch assembly 114 is configured and operates like each locking latch assembly 114 of the filter/lens optical component 106-n of Figs. 2 to 4 except for the following differences. Like the element structure assembly 115 of the grating mirror optical component 215, the locking latch assembly 114 here comprises a hinge 229 instead of a hinge 116 and also comprises an additional support arm 230. The locking latch 121 is pivotally coupled to the moveable stage 225 of the moveable stage assembly 222 by the hinge 229. The slot 122 of the locking latch 121 is sized here to closely receive the corresponding left or right side of the element structure 115 in the locking position of the locking latch 121. Similar to the element structure assembly 113, the support arm 230 is pivotally coupled to the support arm 119 by the hinge 118. A portion of the support arm 230 extends underneath and supports the left or right side of the locking latch 121 that is adjacent to the hinges 117 and 118, the support arm 119, and the actuator

mechanism 120 of the locking latch assembly 114 without being physically coupled to the locking latch 121. The hinges 229, 117, and 118 and the support arm 119 therefore cooperatively translate the lateral forward movement of the actuator mechanism 120 into pivoting movement by the locking latch 121 about the rotation axis R_4 of the hinges 229.

5 This is done under the control of the control circuit 109 of Fig. 17 until the locking latch 121 has been moved from its lying position in Fig. 19 in the first partially assembled state of the grating mirror optical component 215 to its locking position shown in Fig. 20 in the second partially assembled state of the grating mirror optical component 215.

10 Then, under the control of the control circuit 109, the actuator mechanism 120 of each of the element structure and locking latch assemblies 113 and 114 is laterally moved backward in the manner shown in Fig. 21. This removes the hinges 117 and 118 and the support arms 119 and 230 of each of the element structure and locking latch assemblies 113 and 114 away from the moveable stage assembly 222 so that the moveable stage 225 can freely rotate about the rotation axis R_7 . As a result, the grating mirror optical component 215
15 is then in its completely assembled state.

Similar to that described earlier for the filter/lens optical component 106-n of Figs. 2 to 4, the locking latch assembly 114 could be eliminated from the configuration of the grating mirror optical component 215 if the element structure 115 is stable enough for proper optical alignment in its upright position without the locking latch assembly 114. Or, more than one
20 locking latch assembly 114 may be used to add even more stability.

Referring back to Fig. 17, in its completely assembled state, the grating mirror optical component 215 is reconfigurable under the control of the control circuit 109 so that it can be properly tuned to spread the input light beam 205 out into its constituent wavelengths including the wavelengths λ_1 to λ_M to produce the wide spectrum light beam 209.
25 Specifically, under the control of the control circuit 109, the actuator mechanism 120 of the moveable stage assembly 222 can be controlled to move along an arc so as to cause the moveable stage 225 to rotate about the rotation axis R_7 and properly position the element structure 115 in the path of the input light beam 205.

Element Structure Assembly 113

Fig. 22 shows the configuration of the element structure 115 of the element structure assembly 113 in Figs. 18 to 21 of the grating mirror optical component 215. Similar to the element structure 115 of Fig. 5 of each filter/lens optical component 106-n of Figs. 2 to 4, the element structure 115 comprises a support plate 127. However, here, the element structure 115 comprises a grating mirror optical element 232 formed on the support plate 127. The grating mirror optical element 232 comprises a metal plate 231 with vertical metal strips 233 formed on the support plate 127. Alternatively, the support plate 127 could be etched to form a pattern of vertical strips in the support plate 127 coated with metal to produce the grating mirror optical element 232. The grating mirror optical element 232 is therefore configured to optically interact with the input light beam 205 of Fig. 17 to spread it out into its constituent wavelengths including the wavelengths λ_1 to λ_M to produce the wide spectrum light beam 209.

Each hinge 229 of the element structure assembly 113 of Figs. 18 to 21 is configured and operates similar to each hinge 116 shown in Figs. 7 to 9 of each filter/lens optical component 106-n of Figs. 2 to 4. However, as shown in Figs. 23 to 25, there are a few significant differences that will be discussed next. Each hinge 229 does not include a base 138 and anchors 134 since its hinge plate 130 is fixedly coupled to the moveable stage 225 of the moveable stage assembly 222. In fact, the hinge plate 130 may be integrally formed with the moveable stage 225. Furthermore, the hinge plate 133 is fixedly coupled to and may be integrally formed with the support plate 127 of the element structure 115.

The hinges 117 and 118, the support arm 119, and the actuator 120 of the element structure assembly 113 have a similar configuration and operation to those described earlier and shown in Figs. 10 to 13 for each filter/lens optical component 106-n of Figs. 2 to 4. However, referring to Figs. 26 and 27, the element structure assembly 113 also comprises an additional support arm 230.

This support arm 230 is fixedly coupled to the hinge plate 130 of the hinge 118 by a via 148. A portion of the support arm 230 extends underneath and supports the left or right side of the element structure 115 that is adjacent to the hinges 117 and 118, the support arm

119, and the actuator mechanism 120 of the element structure assembly 113 without being physically coupled to the element structure 115.

Locking latch assembly 114

5 The locking latch 121 of the locking latch assembly 114 of the grating mirror optical component 215 of Figs. 18 to 21 has a similar configuration and operation to that shown in Fig. 6 for the filter/lens optical component 106-n of Figs. 2 to 4. However, as mentioned earlier, the slot 122 of the locking latch 121 here is sized to closely receive the corresponding left or right side of the element structure 115 in the locking position of the locking latch 121.

10 Each hinge 229 of the locking latch assembly 114 of Figs. 18 to 21 is configured and operates similar to that shown in Figs. 23 to 25 except for one major difference. Here, the hinge plate 133 is fixedly coupled to and may be integrally formed with the locking latch 121. And, pivoting of the hinge plate 133 and the locking latch 121 and rotation of the hinge pin 131 occurs about the rotation axis R_4 .

15 The hinges 117 and 118, the support arm 119, and the actuator 120 of the locking latch assembly 114 have a similar configuration and operation to those described earlier and shown in Figs. 10 to 13 for each filter/lens optical component 106-n of Figs. 2 to 4. However, similar to the element structure assembly 113, the locking latch assembly 114 also comprises an additional support arm 230 that is configured and operates similar to that shown in Figs. 26 and 27. However, here, a portion of the support arm 230 extends underneath and
20 supports the left or right side of the locking latch 121 that is adjacent to the hinges 117 and 118, the support arm 119, and the actuator mechanism 120 of the locking latch assembly 114 without being physically coupled to the locking latch 121.

Moveable stage Assembly 222

25 Fig. 28 shows the configuration of the rotation hinge 226. The rotation hinge 226 comprises a lower bracket 235, a middle section 236, an anchor 154, and an upper bracket 237. The lower bracket 235 is fixedly coupled to the insulating layer 111. The middle section 236 is oriented in a horizontal plane and also has an opening 238 that is oriented in

the horizontal plane. The anchor 154 is located within the opening 238 and extends down along the rotation axis R_7 of the rotation hinge 226. This anchor 154 fixedly couples the lower and upper brackets 235 and 237 together. The upper and lower brackets 235 and 237 are oriented parallel to the horizontal plane and have dimensions (i.e., cross sectional widths) parallel to the plane that are greater than the dimension (i.e., diameter) of the opening 238. As a result, movement of the middle section 236 relative to the lower and upper brackets 235 and 237 is limited to rotation in the horizontal plane about the rotation axis R_7 . Thus, the anchor 154 serves as the hinge pin of the rotation hinge 226.

The moveable stage 225 is fixedly coupled to the middle section 236 of the rotation hinge 226. In fact, the moveable stage 225 may be integrally formed with the middle section 236. This enables the moveable stage 225 to rotate about the rotation axis R_7 of the rotation hinge 226 as the middle section 236 rotates about the rotation axis R_7 .

Referring back to Figs. 18 to 21, the actuator mechanism 120 of the grating mirror optical component 215 comprises two actuator sub-mechanisms 142. Figs. 29 and 30 show the configuration of each actuator sub-mechanism 120 of the grating mirror optical component 215. Except for a few differences to be discussed next, each actuator sub-mechanism 120 is configured and operates similar to the actuator sub-mechanism 142 shown in Figs. 14 to 16 and described earlier for each filter/lens optical component 106-n of Figs. 2 to 4. One of the actuator sub-mechanisms 142 is configured for clockwise movement along an arc and the other is configured for counter clockwise movement along the arc. Thus, the bias lines 150 and the contact rails 149 are arc shaped so that each actuator sub-mechanism 142 can travel along an arc. Furthermore, in the actuator sub-mechanism 142 configured for clockwise movement, the SDAs 144 are aligned for clockwise movement. Conversely, the SDAs 144 are aligned for counter clockwise movement in the actuator sub-mechanism 142 configured for counter clockwise movement. Furthermore, each actuator sub-mechanism 142 includes an insulating attachment bridge 141 that fixedly couples the support frame 143 of the actuator sub-mechanism 142 and the moveable stage 225.

The moveable stage assembly 222 further comprises a guide strip 241 that is ring shaped. Correspondingly, the moveable stage 225 comprises a contact rail 242 that is ring

shaped. The contact rail 242 slides on the guide strip 241 as the moveable stage 225 rotates. The contact rail 242 therefore enables the moveable stage 225 to rotatably slide on the guide strip 241 with minimal friction and stiction.. The contact rail 242 may be continuous or may comprise a circle of protrusions or bumps.

5 Referring back to Figs. 18 to 21, the moveable stage assembly 222 could further comprise guiding overhangs 140 similar to those of the moveable stage assembly 260 of Fig. 33. In this case, the guide strip 241 of Fig. 30 would extend out past the circumference of the moveable stage 225 so that the guiding overhangs 140 could be fixedly coupled to the guide strip 241 with anchors 154.

10 Furthermore, the moveable stage 225 could be crescent moon shaped with an opening that is closely sized to fit around the left and right sides of the element structure 115 and extends into the moveable structure until just before the rotation hinge 226 and the hinges 229 of the element structure assembly 113. This would ensure that the portion of the support plate 127 under the metal strips 233 of the grating mirror optical element 232 would be made
15 flat during fabrication. As a result, the metal strips 233 of the grating mirror optical element 232 would be formed on a flat surface.

Gate Filter Array 216

As mentioned earlier, the gate filter array 216 of Fig. 17 comprises MEMS gate filter optical components 218-1 to M. Each gate filter optical component 218-m is configured to
20 pass a corresponding wavelength λ_m from among the other constituent wavelengths of the input light beam 205 that are around the wavelength λ_m . Like each filter/lens optical component 106-n of Figs. 2 to 4, each gate filter optical component 218-m is monolithically fabricated on the chip 104 and is self assemblable on the chip 104 under the control of the control circuit 109. Furthermore, the configuration, operation, and self assembly of each gate
25 filter optical component 218-m is similar to that of each filter/lens optical component 106-n except for the differences that are discussed next.

Fig. 31 shows the configuration of each gate filter optical component 218-m in its unassembled state. Similar to each lens/filter optical component 106-n, each gate filter

optical component 218-m comprises an element structure assembly 113 and a locking latch assembly 114. Here, however, the element structure 115 comprises a support plate 127 and a gate filter optical element 247 formed on/in the support plate 127. Specifically, the gate filter optical element 247 comprises a slot 248 formed in the support plate 127. Furthermore, the slot 122 of the locking latch 121 of the locking latch assembly 114 is sized to closely receive the corresponding left or right side of the element structure 115 in the locking position of the locking latch 121. The gate filter optical element 247 is configured to optically interact with the wide spectrum light beam 209 in Fig. 17 to extract the corresponding wavelength λ_m produce the corresponding filtered light beam 213-m.

The partially assembled and completely assembled states of each gate filter optical component 218-m are similar to those of each filter/lens optical component 106-n shown in Figs. 3 and 4, respectively. Except for the few differences just discussed, the element structure assembly 113 and the locking latch assembly 114 are otherwise configured and operate similar to the element structure assembly 113 and locking latch assemblies 114 in Figs. 2 to 4 of each filter/lens optical component 106-n.

Refractive Lens Array 217

Referring back to Fig. 17, the refractive lens array 217 comprises MEMS refractive lens optical components 219-1 to M, as mentioned earlier. Each refractive lens optical component 219-m is configured to re-focus a corresponding wavelength λ_m to produce the corresponding individual light beam 210-m with the wavelength λ_m . Like each filter/lens optical component 106-n of Figs. 2 to 4, each refractive lens optical component 219-m is monolithically fabricated on the chip 104 and self assemblable on the chip 104 under the control of the control circuit 109. Furthermore, the configuration, operation, and self assembly of each refractive lens optical component 219-m is similar to that of each filter/lens optical component 106-n except for the differences that are discussed next.

Fig. 32 shows the configuration of refractive lens optical component 219-m in its unassembled state. Similar to each lens/filter optical component 106-n, each refractive lens optical component 219-m comprises an element structure assembly 113 and a locking latch

assembly 114. Here, however, the element structure 115 comprises a support plate 127 and a refractive lens optical element 252 formed on the support plate 127. The refractive lens optical element 252 is shaped and configured to optically interact with the corresponding filtered light beam 213-m by focusing it to the attenuator array 208 of Fig. 17 as the
5 corresponding individual light beam 210-m. Correspondingly, the refractive lens component 219-m is configured on the chip 104 in Fig. 17 in order to accomplish this function. The slot 122 of the locking latch 121 of the locking latch assembly 114 is sized to closely receive the corresponding left or right side of the element structure 115 in the locking position of the locking latch 121.

10 The partially assembled and completely assembled states of each refractive lens optical component 219-m are similar to those of each filter/lens optical component 106-n shown in Figs. 3 and 4, respectively. Except for the few differences just discussed, the element structure assembly 113 and the locking latch assembly 114 are otherwise configured and operate similar to the element structure assembly 113 and locking latch assemblies 114 in
15 Figs. 2 to 4 of each filter/lens optical component 106-n.

Attenuator Array 208

Referring back to Fig. 17, the attenuator array 208 comprises MEMS attenuators 255-1 to M for separately regulating the power levels of the individual light beams 210-1 to M by separately attenuating them. This produces the separately regulated light beams 211-1
20 to M with respective wavelengths λ_1 to λ_M and respective regulated power levels. In doing so, each attenuator 255-m is configured to regulating the power level of a corresponding individual light beam 210-m by attenuating it. This results in a corresponding regulated light beam 211-m with a corresponding wavelength λ_m and corresponding regulated power level. Each attenuator 255-m is monolithically fabricated on the chip 104 and is self assemblable on
25 and reconfigurable on the chip 104 under the control of the control circuit 109. Thus, the entire attenuator array 208 is itself self assemblable on and reconfigurable on the chip 104 under the control of the control circuit 109.

Each attenuator 255-m comprises a corresponding MEMS refractive lens optical component 256-m, a MEMS gate filter optical component 218-m, and a MEMS refractive lens optical component 259-m. The refractive lens optical component 256-m, the gate filter optical component 218-m, and the refractive lens optical component 259-m are all monolithically fabricated on the chip 104 and self assemblable on the chip 104 under the control of the control circuit 109.

In its completely assembled state, the refractive lens optical component 256-m is configured on the chip 104 to diverge the corresponding individual light beam 210-m to produce a divergent light beam 257-m with the corresponding wavelength λ_m . The gate filter optical component 218-m, in its completely assembled state, allows only a portion of the divergent light beam 257-m to pass through it. This attenuates the power level of the divergent light beam 257-m and produces the corresponding attenuated light beam 258-m with the corresponding wavelength λ_m at the attenuated power level. In its completely assembled state, the refractive lens optical component 256-m is reconfigurable under the control of the control circuit 109 in that it can be laterally moved forward and/or backward in the path of the corresponding individual light beam 210-m to regulate the amount of the divergent light beam 257-m that passes through the gate filter optical component 218-m. In this way, the attenuated power level of the attenuated light beam 258-m can be regulated under the control of the control circuit 109. The refractive lens optical component 259-m, in its completely assembled state, is configured on the chip 104 to converge the attenuated light beam 258-m. This produces the corresponding regulated light beam 211-m with the corresponding wavelength λ_m and corresponding regulated power level that was discussed earlier.

Refractive Lens Optical Component 256-m

Fig. 33 shows the configuration of each refractive lens optical component 256-m in its unassembled state. Each refractive lens optical component 256-m comprises a moveable stage assembly 260, an element structure assembly 113, and a locking latch assembly 114.

The moveable stage assembly 260 is configured and operates in a similar manner to the moveable stage assembly 220 of the grating mirror optical component 215 of Figs. 18 to 21. Here, however, the moveable stage assembly 260 comprises a moveable stage 262, a guide plate 263, corresponding guiding overhangs 140, and a corresponding actuator mechanism 120. To enable the moveable stage 262 to laterally move forward and backward, the moveable stage 262, the guide plate 263, the corresponding guiding overhangs 140, and the corresponding actuator mechanism 120 are configured and operate in a similar manner to the hinge plate 130, the guide plate 139, the corresponding guiding overhangs 140, and the corresponding actuator mechanism 120 in Figs. 10 to 16 of the element structure assembly 113 of Figs. 2 to 4.

Specifically, the moveable stage 262 comprises contact rails 149 (not shown) like those of the hinge plate 130 in Fig. 13 to enable the moveable stage 262 to laterally slide on the guide plate 263 with minimal friction and stiction. Each contact rail 149 (not shown) may be continuous or may comprise a row of protrusions or bumps. The guiding overhangs 140 are fixedly coupled to the guide plate 263 with anchors 154 (not shown) and together guide the moveable stage 262 as it moves laterally on the guide plate 263. Furthermore, the moveable stage 262 is fixedly coupled to the actuator mechanism 120 with the insulating attachment bridge 141.

Similar to each refractive lens optical component 219-m in Fig. 33, the element structure assembly 113 of each refractive lens optical component 256-m comprises an element structure 115 that comprises a support plate 127 and a refractive lens optical element 265 formed on the support plate 127. Here, the refractive lens optical element 265 is shaped and configured to optically interact with the corresponding individual light beam 210-m in Fig. 17 by diverging it to produce the corresponding divergent light beam 257-m. Correspondingly, the refractive lens component 256-m is configured on the chip 104 in Fig. 17 in order to accomplish this function.

Furthermore, similar to the element structure assembly 113 in Figs. 18 to 21 of the grating mirror optical component 215, the element structure assembly 113 here comprises hinges 229. The element structure 115 is pivotally coupled to the moveable stage 262 by the

hinges 229 in a similar manner in which the hinges 229 in Figs. 18 to 21 of the element structure assembly 113 pivotally couple the element structure 115 there to the moveable stage 225. The hinges 229 are each configured like that shown in Figs. 23 to 25.

Like the moveable stage 225 of Figs. 18 to 21, the moveable stage 262 could be crescent moon shaped with an opening that is closely sized to fit around the left and right sides of the element structure 115 and extends into the moveable structure 262 until just before the rotation hinge 226 and the hinges 229 of the element structure assembly 113. This would ensure that the portion of the support plate 127 under the refractive lens optical element 265 would be made flat during fabrication. As a result, the refractive lens optical element 265 of the grating mirror 232 would be formed on a flat surface.

The locking latch assembly 114 here also comprises hinges 229. These hinges 229 pivotally couple the locking latch 121 to the moveable stage 262. This is done in a similar manner in which the hinges 229 in Figs. 18 to 21 of the locking latch assembly 114 of the grating mirror optical component 215 pivotally couple the locking latch 121 there to the moveable stage 225. The hinges 229 here are each also configured like that shown in Figs. 23 to 25 except that the hinge plate 133 is fixedly coupled to the locking latch 121. The slot 122 of the locking latch 121 of the locking latch assembly 114 is sized to closely receive the corresponding left or right side of the element structure 115 in the locking position of the locking latch 121.

The first partially assembled, second partially assembled, and completely assembled states of each refractive lens optical component 256-m are similar to those of the grating mirror optical component 215 shown in Figs. 19, 20, and 21, respectively. Here, however, the moveable stage assembly 260 is substituted for the moveable stage assembly 222 and a different element structure 115 is used. Except for the differences just discussed, the moveable stage assembly 260, the element structure assembly 113, and the locking latch assembly 114 are otherwise configured and operate similar to the moveable stage assembly 222, the element structure assembly 113, and the locking latch assembly 114 in Figs. 18 to 21 of the grating mirror optical component 215.

As mentioned before, in its completely assembled state, the refractive lens optical component 256-m is reconfigurable under the control of the control circuit 109 in that it can be laterally moved forward and/or backward in the path of the corresponding individual light beam 210-m to regulate the amount of the divergent light beam 257-m that passes through the gate filter optical component 218-m. Specifically, under the control of the control circuit 109, the actuator mechanism 120 of the moveable stage assembly 260 can be controlled to move laterally forward or backward so as to cause the moveable stage 225 to move laterally forward or backward in the path of the corresponding individual light beam 210-m and properly position the element structure 115 in the path of the input light beam 210-m.

Gate Filter Optical Component 218-m

The configuration, operation, and self assembly of the gate filter optical component 218-m of each attenuator 255-m is similar to that described earlier for each gate filter optical component 218-m of the gate filter array 216 of the MUX/DMUX 207-1. Therefore, that description applies here as well to the gate filter optical component 218-m of each attenuator 255-m.

Refractive Lens Optical Component 259-m

Fig. 34 shows the configuration of each refractive lens optical component 259-m of each attenuator 255-m in its unassembled state. Except for the differences that will be discussed next, the configuration, operation, and self assembly of the refractive lens optical component 259-m of each attenuator 255-m is similar to that described earlier for each refractive lens optical component 219-m in Fig. 32 of the refractive lens array 217 of Fig. 17.

The refractive lens optical component 259-m comprises an element structure 115 like that shown in Fig. 33 for the refractive lens optical component 256-m. The refractive lens optical element 265 is shaped for converging the corresponding attenuated light beam 258-m to produce the corresponding regulated light beam 211-m. Correspondingly, the refractive lens component 259-m is configured on the chip 104 in Fig. 17 in order to accomplish this function.

MUX/DMUX 207-2

Referring back to Fig. 17, in contrast to the MUX/DMUX 207-1, the MUX/DMUX 207-2 is configured on the chip 104 and used in the optical network 200 for multiplexing.

5 The MUX/DMUX 207-2 has otherwise the same configuration and self-assembly as the MUX/DMUX 207-1. Furthermore, the operation of the MUX/DMUX 207-2 in the optical network 100 is the reciprocal of that discussed for the MUX/DMUX 207-1.

Fabrication Process

10 The WDM power regulator 203 may be fabricated using a three polysilicon layer process. This of course also means that the MUX/DMUXs 207-1 and 207-2, the attenuator array 208, the grating mirror optical component 215, the gate filter array 216, the refractive lens array 217, each attenuator 255-m, each gate filter optical component 218-m, each refractive lens optical component 219-m, each refractive lens optical component 256-m, each refractive lens optical component 259-m, and each attenuator 270-m may each be formed
15 with this same three polysilicon layer process.

This three polysilicon layer process is similar to that described earlier for the MUX/DMUX 103. In fact, the formation of elements with the same reference numerals as in the MUX/DMUX 103 will be the same. As a result, only the differences in the three polysilicon layer process with respect to formation of new elements will be discussed next.

20 Here, the first polysilicon layer (poly 0) is further selectively patterned on the insulating layer 111 to form the guide strip 241 in Fig. 30 of each moveable stage assembly 222, the lower bracket 235 in Fig. 28 of each rotation hinge 226, and the guide plate 263 in Fig. 33 of each moveable stage assembly 260.

25 The first sacrificial layer is further selectively etched to form dimples in the first sacrificial layer for forming the contact rail 242 in Fig. 30 of each moveable stage 225 and the rails 149 (not shown) of each moveable stage 262 in Fig. 33. Furthermore, the first sacrificial layer is also selectively etched down to the lower bracket 235 in Fig. 28 of each rotation hinge 226 and down to the guide plate 263 in Fig. 33 of each moveable stage

assembly 260 to form openings in the first sacrificial layer for the anchor 154 of each rotation hinge 226 and the anchors 154 (not shown) for the guiding overhangs 140 of each moveable stage assembly 260.

The second polysilicon layer (poly 1) is further deposited in the openings just mentioned. The second polysilicon layer is then further selectively patterned to form the lower portion of the anchors just mentioned, the middle section 236 in Fig. 28 of each rotation hinge 226, the moveable stage 225 in Figs. 28 and 30 including the contact rail 242, the moveable stage 262 in Fig. 33 including the contact rails 149 (not shown), the hinge plate 130 in Figs. 23 to 25 of each hinge 229, and the support arm 230 in Figs. 26 and 27 of each element structure assembly 113 and each locking latch assembly 114.

The second sacrificial layer is further selectively etched down to the support arm 230 in Figs. 26 and 27 of each element structure assembly 113 and each locking latch assembly 114 and down to the hinge plate 130 in Figs. 23 to 25 of each hinge 229 to form openings for the corresponding vias 148. The second sacrificial layer is also selectively etched down to the lower portions of the anchor 154 in Figs. 24 and 25 of each rotation hinge 226 and the anchors 154 (not shown) in Fig. 33 of each moveable stage assembly 260 to form openings for the upper portions of these anchors 154.

The third polysilicon layer (poly 2) is further deposited in the openings just mentioned. The third polysilicon layer is then further selectively patterned to form the upper portions of the anchors 154 just mentioned, the vias 148 just mentioned, the upper bracket 237 of each rotation hinge 226, the hinge plate 133 and locking arm 132 in Figs. 23 to 25 of each hinge 229, and the guiding overhangs 140 in Fig. 33 of each moveable stage assembly 260. The third polysilicon layer (poly 2) is further selectively patterned to form the slot 248 in Fig. 31 in the support plate 127 of the element structure 115 of each gate filter optical component 218-m.

The third sacrificial layer is further selectively etched to down to the support plate 127 in Fig. 22 of the element structure 115 of each grating mirror optical component 215 to form openings for the formation of the metal strips 233.

Then, a metal layer, such as gold, is deposited on the third sacrificial layer in the openings just mentioned. The metal layer is then selectively patterned to form the metal plate 231 and the metal strips 233.

The third sacrificial layer is then further selectively etched down to the support plates 127 in Figs. 32 to 34 of the element structures 115 of each grating mirror optical component 215 and each refractive lens optical component 219-m, 256-m, and 259-m to form openings for the formation of the refractive lenses 252 and 265.

Then, a lens forming layer, such as a polyamide (i.e., a photoresist), silicon nitride, or polysilicon (i.e., a fourth polysilicon layer (poly 3)), is then deposited on the third sacrificial layer and in the openings just mentioned. This layer is then patterned to form the lenses 252 and 265 just mentioned.

Finally, the first, second, and third sacrificial layers are removed. This frees all of the hinges 116, 117, 118, 226, and 229, the element structures 115, the locking latches 121, the moveable stages 225, the moveable stages 262, support arms 230, and the actuator mechanisms 120 in Figs. 18 to 21 and 31 to 34 for movement in the manner described earlier.

Conclusion

The present invention may be embodied as any optical network, such as the optical network 100 of Fig. 1 and/or the network 200 of Fig. 17, that comprises one or more optical input sources and one or more optical output collectors, such as the optical input source 101 and/or the optical output collectors 102-1, 2, 3, 4, ..., N of Fig. 1 and/or the optical input source 201 and/or the optical output collector 202 of Fig. 17, and an optical device, such as the MUX/DMUX 103 of Fig. 1, the WDM power regulator 203 of Fig. 17, the MUX/DMUXs 207-1 and 207-2 of Fig. 17, the attenuator 255-m of Fig. 17, and/or the attenuator 270-m, that is optically coupled between the optical input sources and the optical output collectors and is integrated on an integrated MEMS chip, such as chip 104 of Fig. 1 or Fig. 17. The optical device could additionally be or comprise a switch, a filter apparatus, a wavemeter, a power regulator, an attenuator, and/or some other optical device.

The optical device includes one or more monolithically fabricated, on-chip assemblable, MEMS optical components, such as the filter/lens optical component 105 of Fig. 1, the filter/lens optical components 106-n of Figs. 2 to 4, the grating mirror optical component 215 of Figs. 18 to 21, the gate filter optical component 218-m of Fig. 31, the refractive lens optical component 219-m of Fig. 32, the refractive lens optical component 256-m of Fig. 33, and the refractive lens optical component 259-m of Fig. 34, integrated on the chip in accordance with the invention. These optical components could comprise one or more of a filter, mirror, lens, tuning plate, and/or some other optical component.

Furthermore, some of the elements of the optical components 105, 106-n, 215, 218-m, 219-m, 256-m, and 259-m described herein can be used in other applications. For example, the hinges 116, 117, 118, 226, and 229, the support arms 119, and the actuator mechanisms 120 can be used in quasi-optical systems and RF devices, as disclosed in copending PCT Patent Applications Ser. Nos. _____ and _____, having respective attorney docket nos. FP-68000/JAS/SMK and FP-67999/JAS/SMK, with respective titles MEMS TRANSMISSION AND CIRCUIT COMPONENTS and RECONFIGURABLE QUASI-OPTICAL UNIT CELLS, and filed on June 9, 2000. As mentioned earlier, these copending applications are hereby incorporated by reference.

Finally, while the present invention has been described with reference to a few specific embodiments, the description is illustrative of the invention and is not to be construed as limiting the invention. Various modifications may occur to those skilled in the art without departing from the true spirit and scope of the invention as defined by the appended claims.

What is claimed is:

1. A MEMS optical component formed on a integrated MEMS chip oriented in a horizontal plane, the MEMS optical component comprising:

an element structure assembly comprising:

5 a corresponding actuator mechanism formed on the integrated MEMS chip, the corresponding actuator mechanism being configured to be controlled to move laterally on the integrated MEMS chip;

an element structure formed on and pivotally coupled to the integrated MEMS chip and moveably coupled to the corresponding actuator mechanism, the element structure
10 having a lying position generally parallel to the horizontal plane and an upright position generally perpendicular to the horizontal plane, the element structure comprising an optical element that is configured to optically interact with an input light beam when in the upright position;

wherein, when the corresponding actuator mechanism is controlled to move
15 laterally, the element structure pivots so as to move from the lying position to the upright position so that the optical element optically interacts with the input light beam.

2. The MEMS optical component of claim 1 wherein the element structure assembly further comprises:

a corresponding first hinge configured to pivotally couple the element structure to the
20 insulating layer;

a corresponding support arm, a corresponding second hinge, and a corresponding third hinge configured to moveably couple the element structure to the corresponding actuator mechanism, the corresponding second hinge being configured to pivotally couple a first end of the corresponding support arm to the corresponding actuator mechanism, the
25 corresponding third hinge being configured to pivotally couple a second end of the corresponding support arm to the element structure.

3. The MEMS optical component of claim 2 wherein the MEMS optical component is monolithically fabricated on the integrated MEMS chip.

4. The MEMS optical component of claim 1 further comprising a locking latch assembly, the locking latch assembly comprising:

5 a corresponding actuator mechanism formed on the insulating layer, the corresponding actuator mechanism being configured to be controllably moved laterally with respect to the insulating layer;

a locking latch pivotally coupled to the insulating layer and moveably coupled to the corresponding actuator mechanism, the locking latch having a slot sized to closely receive a side of the element structure, the locking latch having a lying position parallel to the insulating layer and a locking position in which the slot receives the side of the element structure when the element structure is in the upright position;

wherein, when the corresponding actuator mechanism is controlled to move laterally, the locking latch pivots so as to move from the lying position to the locking position.

15 5. The MEMS optical component of claim 1 wherein:
the element structure assembly further comprises:

a corresponding first hinge configured to pivotally couple the element structure to the insulating layer;

20 a corresponding support arm, a corresponding second hinge, and a corresponding third hinge configured to moveably couple the element structure to the corresponding actuator mechanism, the corresponding second hinge being configured to pivotally couple a first end of the corresponding support arm to the corresponding actuator mechanism, the corresponding third hinge being configured to pivotally couple a second end of the corresponding support arm to the element structure; and

25 the locking latch assembly further comprises:

a corresponding first hinge configured to pivotally couple the locking latch to the insulating layer;

a corresponding support arm, a corresponding second hinge, and a corresponding third hinge configured to moveably couple the locking latch to the corresponding actuator mechanism of the locking latch assembly, the corresponding second hinge being configured to pivotally couple a first end of the corresponding support arm to the corresponding actuator mechanism of the locking latch assembly, the corresponding third hinge being configured to pivotally couple a second end of the corresponding support arm to the locking latch.

6. The MEMS optical component of claim 5 wherein the MEMS optical component is monolithically fabricated on the integrated MEMS chip.

7. An optical device integrated on an integrated MEMS chip, the integrated MEMS chip being oriented in a horizontal plane, the optical device comprising one or more MEMS optical components, each of the MEMS optical components comprising:

an element structure assembly comprising:

a corresponding actuator mechanism formed on the integrated MEMS chip, the corresponding actuator mechanism being configured to be controlled to move laterally on the integrated MEMS chip;

an element structure formed on and pivotally coupled to the integrated MEMS chip and moveably coupled to the corresponding actuator mechanism, the element structure having a lying position generally parallel to the horizontal plane and an upright position generally perpendicular to the horizontal plane, the element structure comprising an optical element that is configured to optically interact with an input light beam when in the upright position;

wherein, when the corresponding actuator mechanism is controlled to move laterally, the element structure pivots so as to move from the lying position to the upright position so that the optical element can optically interact with the input light beam.

8. The optical device of claim 7 wherein the element structure assembly of each MEMS optical component further comprises:

a corresponding first hinge configured to pivotally couple the element structure to the insulating layer;

5 a corresponding support arm, a corresponding second hinge, and a corresponding third hinge configured to moveably couple the element structure to the corresponding actuator mechanism, the corresponding second hinge being configured to pivotally couple a first end of the corresponding support arm to the corresponding actuator mechanism, the corresponding third hinge being configured to pivotally couple a second end of the
10 corresponding support arm to the element structure.

9. The optical device of claim 8 wherein each of the MEMS optical components is monolithically fabricated on the integrated MEMS chip.

10. The optical device of claim 7 wherein each of the MEMS optical components further comprises a locking latch assembly, the locking latch assembly comprising:

15 a corresponding actuator mechanism formed on the insulating layer, the corresponding actuator mechanism being configured to be controllably moved laterally with respect to the insulating layer;

a locking latch pivotally coupled to the insulating layer and moveably coupled to the corresponding actuator mechanism, the locking latch having a slot sized to closely receive a
20 side of the element structure, the locking latch having a lying position parallel to the insulating layer and a locking position in which the slot receives the side of the element structure when the element structure is in the upright position;

wherein, when the corresponding actuator mechanism is controlled to move laterally, the locking latch pivots so as to move from the lying position to the locking position.

25 11. The optical device of claim 10 wherein:

the element structure assembly of each of the MEMS optical components further comprises:

a corresponding first hinge configured to pivotally couple the element structure to the insulating layer;

5 a corresponding support arm, a corresponding second hinge, and a corresponding third hinge configured to moveably couple the element structure to the corresponding actuator mechanism, the corresponding second hinge being configured to pivotally couple a first end of the corresponding support arm to the corresponding actuator mechanism, the corresponding third hinge being configured to pivotally couple a second end
10 of the corresponding support arm to the element structure; and

the locking latch assembly of each of the MEMS optical components further comprises:

a corresponding first hinge configured to pivotally couple the locking latch to the insulating layer;

15 a corresponding support arm, a corresponding second hinge, and a corresponding third hinge configured to moveably couple the locking latch to the corresponding actuator mechanism of the locking latch assembly, the corresponding second hinge being configured to pivotally couple a first end of the corresponding support arm to the corresponding actuator mechanism of the locking latch assembly, the corresponding third
20 hinge being configured to pivotally couple a second end of the corresponding support arm to the locking latch.

12. The MEMS optical component of claim 11 wherein each of the MEMS optical components is monolithically fabricated on the integrated MEMS chip.

13. An optical network comprising:

25 one or more optical input sources;
one or more optical output collectors; and

an optical device optically coupled between the one or more optical input sources and the one or more optical output collectors, the optical device being formed on a integrated MEMS chip, the integrated MEMS chip being oriented in a horizontal plane, the optical device comprising one or more MEMS optical components, each of the MEMS optical components comprising:

an element structure assembly comprising:

a corresponding actuator mechanism formed on the integrated MEMS chip, the corresponding actuator mechanism being configured to be controlled to move laterally on the integrated MEMS chip;

an element structure formed on and pivotally coupled to the integrated MEMS chip and moveably coupled to the corresponding actuator mechanism, the element structure having a lying position generally parallel to the horizontal plane and an upright position generally perpendicular to the horizontal plane, the element structure comprising an optical element that is configured to optically interact with an input light beam when in the upright position;

wherein, when the corresponding actuator mechanism is controlled to move laterally, the element structure pivots so as to move from the lying position to the upright position so that the optical element can optically interacting with the input light beam.

14. The optical network of claim 13 wherein the element structure assembly of each MEMS optical component further comprises:

a corresponding first hinge configured to pivotally couple the element structure to the insulating layer;

a corresponding support arm, a corresponding second hinge, and a corresponding third hinge configured to moveably couple the element structure to the corresponding actuator mechanism, the corresponding second hinge being configured to pivotally couple a first end of the corresponding support arm to the corresponding actuator mechanism, the

corresponding third hinge being configured to pivotally couple a second end of the corresponding support arm to the element structure.

15. The optical network of claim 15 wherein each of the MEMS optical components is monolithically fabricated on the integrated MEMS chip.

5 16. The optical network of claim 13 wherein each of the MEMS optical components further comprises a locking latch assembly, the locking latch assembly comprising:

a corresponding actuator mechanism formed on the insulating layer, the corresponding actuator mechanism being configured to be controllably moved laterally with respect to the insulating layer;

10 a locking latch pivotally coupled to the insulating layer and moveably coupled to the corresponding actuator mechanism, the locking latch having a slot sized to closely receive a side of the element structure, the locking latch having a lying position parallel to the insulating layer and a locking position in which the slot receives the side of the element structure when the element structure is in the upright position;

15 wherein, when the corresponding actuator mechanism is controlled to move laterally, the locking latch pivots so as to move from the lying position to the locking position.

17. The optical network of claim 16 wherein:

the element structure assembly of each of the MEMS optical components further comprises:

20 a corresponding first hinge configured to pivotally couple the element structure to the insulating layer;

a corresponding support arm, a corresponding second hinge, and a corresponding third hinge configured to moveably couple the element structure to the corresponding actuator mechanism, the corresponding second hinge being configured to
25 pivotally couple a first end of the corresponding support arm to the corresponding actuator

mechanism, the corresponding third hinge being configured to pivotally couple a second end of the corresponding support arm to the element structure; and

the locking latch assembly of each of the MEMS optical components further comprises:

5 a corresponding first hinge configured to pivotally couple the locking latch to the insulating layer,

 a corresponding support arm, a corresponding second hinge, and a corresponding third hinge configured to moveably couple the locking latch to the corresponding actuator mechanism of the locking latch assembly, the corresponding second
10 hinge being configured to pivotally couple a first end of the corresponding support arm to the corresponding actuator mechanism of the locking latch assembly, the corresponding third hinge being configured to pivotally couple a second end of the corresponding support arm to the locking latch.

18. The MEMS optical component of claim 17 wherein each of the MEMS optical
15 components is monolithically fabricated on the integrated MEMS chip.

19. A MEMS optical component formed on an integrated MEMS chip, the MEMS optical component comprising:

 a moveable stage assembly comprising:

 an actuator mechanism formed on the integrated MEMS chip, the actuator
20 mechanism being configured to be controlled to move on the integrated MEMS chip;

 a moveable stage formed on the integrated MEMS chip and fixedly coupled to the actuator mechanism, the moveable stage being configured to be moved on the integrated MEMS chip;

 an element structure coupled to the moveable stage and comprising an optical
25 element;

 wherein, when the actuator mechanism is controlled to move, the moveable stage moves the element structure.

20. An optical device integrated on a integrated MEMS chip, the optical device comprising one or more MEMS optical components, each of the MEMS optical components comprising:

a moveable stage assembly comprising:

5 an actuator mechanism formed on the integrated MEMS chip, the actuator mechanism being configured to be controlled to move on the integrated MEMS chip;

a moveable stage formed on the integrated MEMS chip and fixedly coupled to the actuator mechanism, the moveable stage being configured to be moved on the integrated MEMS chip;

10 an element structure coupled to the moveable stage and comprising an optical element;

wherein, when the actuator mechanism is controlled to move, the moveable stage moves the element structure.

21. An optical network comprising:

15 one or more optical input sources;

one or more optical output collectors; and

an optical device optically coupled between the one or more optical input sources and the one or more optical output collectors, the optical device being formed on a integrated MEMS chip, the optical device comprising one or more MEMS optical components, each of the MEMS optical components comprising:

20 a moveable stage assembly comprising:

an actuator mechanism formed on the integrated MEMS chip, the actuator mechanism being configured to be controlled to move on the integrated MEMS chip;

25 a moveable stage formed on the integrated MEMS chip and fixedly coupled to the actuator mechanism, the moveable stage being configured to be moved on the integrated MEMS chip;

an element structure coupled to the moveable stage and comprising an optical element;

wherein, when the actuator mechanism is controlled to move, the moveable stage moves the element structure.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US00/16023

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

Please See Extra Sheet.

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☒ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

☐
☐

The additional search fees were accompanied by the applicant's protest.

No protest accompanied the payment of additional search fees.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US00/16023

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING

This ISA found multiple inventions as follows:

This application contains the following inventions or groups of inventions which are not so linked as to form a single inventive concept under PCT Rule 13.1.

Group I, claims 1-18, drawn to a micro-electro-mechanical system having specific element structure assembly, classified in class 359, subclass 290.

Group II, claims 19-21, drawn to a micro-electro-mechanical system having specific moveable stage assembly, classified in class 359, subclass 290.

The inventions listed as Groups I and II do not relate to a single inventive concept under PCT Rule 13.1 because, under PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons: Patentability of each invention does not depend on patentability of the other invention. Each invention has acquired a separate status in the art because of their divergent subject matter as pointed out above.

Applicant UNIVERSITY OF HAWAII		

1. This international preliminary examination report has been prepared by this International Preliminary Examining Authority and is transmitted to the applicant according to Article 36.

2. This REPORT consists of a total of 4 sheets.

☐ This report is also accompanied by ANNEXES, i.e., sheets of the description, claims and/or drawings which have been amended and are the basis for this report and/or sheets containing rectifications made before this Authority. (see Rule 70.16 and Section 607 of the Administrative Instructions under the PCT).

These annexes consist of a total of 0 sheets.

3. This report contains indications relating to the following items:

- I ☒ Basis of the report
- II ☐ Priority
- III ☐ Non-establishment of report with regard to novelty, inventive step or industrial applicability
- IV ☒ Lack of unity of invention
- V ☒ Reasoned statement under Article 35(2) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement
- VI ☐ Certain documents cited
- VII ☐ Certain defects in the international application
- VIII ☐ Certain observations on the international application

INTERNATIONAL PRELIMINARY EXAMINATION REPORT

International application No.

PCT/US00/16023

I. Basis of the report

1. With regard to the elements of the international application:*

☒ the international application as originally filed☒ the description:

pages 1-42, as originally filed
pages NONE, filed with the demand
pages NONE, filed with the letter of

☒ the claims:

pages 43-52, as originally filed
pages NONE, as amended (together with any statement) under Article 19
pages NONE, filed with the demand
pages NONE, filed with the letter of

☒ the drawings:

pages 1-32, as originally filed
pages NONE, filed with the demand
pages NONE, filed with the letter of

☒ the sequence listing part of the description:

pages NONE, as originally filed
pages NONE, filed with the demand
pages NONE, filed with the letter of

2. With regard to the language, all the elements marked above were available or furnished to this Authority in the language in which the international application was filed, unless otherwise indicated under this item.

These elements were available or furnished to this Authority in the following language which is:

- ☐ the language of a translation furnished for the purposes of international search (under Rule 23.1(b)).
☐ the language of publication of the international application (under Rule 48.3(b)).
☐ the language of the translation furnished for the purposes of international preliminary examination (under Rules 55.2 and/or 55.3).

3. With regard to any nucleotide and/or amino acid sequence disclosed in the international application, the international preliminary examination was carried out on the basis of the sequence listing:

- ☐ contained in the international application in printed form.
☐ filed together with the international application in computer readable form.
☐ furnished subsequently to this Authority in written form.
☐ furnished subsequently to this Authority in computer readable form.
☐ The statement that the subsequently furnished written sequence listing does not go beyond the disclosure in the international application as filed has been furnished.
☐ The statement that the information recorded in computer readable form is identical to the written sequence listing has been furnished.

4. ☒ The amendments have resulted in the cancellation of:

☒ the description, pages NONE
☒ the claims, Nos. NONE
☒ the drawings, sheets/fig NONE

5. ☐ This report has been drawn as if (some of) the amendments had not been made, since they have been considered to go beyond the disclosure as filed, as indicated in the Supplemental Box (Rule 70.2(c)).**

* Replacement sheets which have been furnished to the receiving Office in response to an invitation under Article 14 are referred to in this report as "originally filed" and are not annexed to this report since they do not contain amendments (Rules 70.16 and 70.17).

**Any replacement sheet containing such amendments must be referred to under item 1 and annexed to this report.

INTERNATIONAL PRELIMINARY EXAMINATION REPORT

International application No.

PCT/US00/16023

IV. Lack of unity of invention

1. In response to the invitation to restrict or pay additional fees the applicant has:

- ☐ restricted the claims.
- ☐ paid additional fees.
- ☐ paid additional fees under protest.
- ☐ neither restricted nor paid additional fees.

2. ☒ This Authority found that the requirement of unity of invention is not complied with and chose, according to Rule 68.1, not to invite the applicant to restrict or pay additional fees.

3. This Authority considers that the requirement of unity of invention in accordance with Rules 13.1, 13.2 and 13.3 is

- ☐ complied with.
- ☒ not complied with for the following reasons:

This application contains the following inventions or groups of inventions which are not so linked as to form a single inventive concept under PCT Rule 13.1.

Group I, claims 1-18, drawn to a micro-electro-mechanical system having specific element structure assembly, classified in class 359, subclass 290.

Group II, claims 19-21, drawn to a micro-electro-mechanical system having specific moveable stage assembly, classified in class 359, subclass 290.

The inventions listed as Groups I and II do not relate to a single inventive concept under PCT Rule 13.1 because, under PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons: Patentability of each invention does not depend on patentability of the other invention. Each invention has acquired a separate status in the art because of their divergent subject matter as pointed out above.

4. Consequently, the following parts of the international application were the subject of international preliminary examination in establishing this report:

- ☒ all parts.
- ☐ the parts relating to claims Nos. .

INTERNATIONAL PRELIMINARY EXAMINATION REPORT

International application No.

PCT/US00/16023

V. Reasoned statement under Article 35(2) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement**1. statement**

Novelty (N)	Claims <u>1-21</u>	YES
	Claims <u>NONE</u>	NO
Inventive Step (IS)	Claims <u>1-21</u>	YES
	Claims <u>NONE</u>	NO
Industrial Applicability (IA)	Claims <u>1-21</u>	YES
	Claims <u>NONE</u>	NO

2. citations and explanations (Rule 70.7)

Claims 1-21 meet the criteria set out in PCT Article 33(2)-(3), because, vis-a-vis the invention of Group I, the prior art does not teach or fairly suggest the lateral movement of the actuator mechanism that is formed on an integrated MEMS chip, the pivotal coupling of an element structure to the integrated MEMS chip, and the moveable coupling of the element structure to the actuator mechanism. Nor does it teach or fairly suggest the pivotal movement of the element structure to an upright position so that an optical element of the element structure optically interacts with an input light beam. For the invention of Group II, the prior art fails to teach or fairly suggest that a moveable stage that is formed on an integrated MEMS chip is fixedly coupled to an actuator mechanism which itself is formed on the integrated MEMS chip, the moveable stage to which an element structure is coupled being configured to be moved on the integrated MEMS chip.

Claims 1-21 meet the criteria set out in PCT Article 33(4), because the claimed invention can be made or deemed useful in industry.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US00/16023

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

Please See Extra Sheet.

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☒ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

☐
☐

- The additional search fees were accompanied by the applicant's protest.
No protest accompanied the payment of additional search fees.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US00/16023

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING

This ISA found multiple inventions as follows:

This application contains the following inventions or groups of inventions which are not so linked as to form a single inventive concept under PCT Rule 13.1.

Group I, claims 1-18, drawn to a micro-electro-mechanical system having specific element structure assembly, classified in class 359, subclass 290.

Group II, claims 19-21, drawn to a micro-electro-mechanical system having specific moveable stage assembly, classified in class 359, subclass 290.

The inventions listed as Groups I and II do not relate to a single inventive concept under PCT Rule 13.1 because, under PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons: Patentability of each invention does not depend on patentability of the other invention. Each invention has acquired a separate status in the art because of their divergent subject matter as pointed out above.

These Notes are intended to give the basic instructions concerning the filing of amendments under Article 19. The Notes are based on the requirements of the Patent Cooperation Treaty and of the Regulations and the Administrative Instructions under that Treaty. In case of discrepancy between these Notes and those requirements, the latter are applicable. For more detailed information, see also the PCT Applicant's Guide, a publication of WIPO.

In these Notes, "Article", "Rule" and "Section" refer to the provisions of the PCT, the PCT Regulations and the PCT Administrative Instructions, respectively.

INSTRUCTIONS CONCERNING AMENDMENTS UNDER ARTICLE 19

The applicant has, after having received the international search report, one opportunity to amend the claims of the international application. It should however be emphasized that, since all parts of the international application (claims, description and drawings) may be amended during the international preliminary examination procedure, there is usually no need to file amendments of the claims under Article 19 except where, e.g. the applicant wants the letter to be published for the purposes of provisional protection or has another reason for amending the claims before international publication. Furthermore, it should be emphasized that provisional protection is available in some States only.

What parts of the international application may be amended ?

The claims only.

The description and the drawings may only be amended during international preliminary examination under Chapter II.

When ? Within 2 months from the date of transmittal of the international search report or 16 months from the priority date, whichever time limit expires later. It should be noted, however, that the amendments will be considered as having been received on time if they are received by the International Bureau after the expiration of the applicable time limit but before the completion of the technical preparations for international publication (Rule 46.1).

Where not to file the amendments ?

The amendments may only be filed with the International Bureau and not with the receiving Office or the International Searching Authority (Rule 46.2).

Where a demand for international preliminary examination has been/is filed, see below.

How ? Either by cancelling one or more entire claims, by adding one or more new claims or by amending the text of one or more of the claims as filed.

A replacement sheet must be submitted for each sheet of the claims which, on account of an amendment or amendments, differs from the sheet originally filed.

All the claims appearing on a replacement sheet must be numbered in Arabic numerals. Where a claim is cancelled, no renumbering of the other claims is required. In all cases where claims are renumbered, they must be renumbered consecutively (Administrative Instructions, Section 205(b)).

What documents must/may accompany the amendments ?

Letter (Section 205(b)):

The amendments must be submitted with a letter.

The letter will not be published with the international application and the amended claims. It should not be confounded with the "Statement under Article 19(1)" (see below, under "Statement under Article 19(1)").

The letter must indicate the differences between the claims as filed and the claims as amended. It must, in particular, indicate, in connection with each claim appearing in the international application (it being understood that identical indications concerning several claims may be grouped), whether

- (i) the claim is unchanged;
- (ii) the claim is cancelled;
- (iii) the claim is new;
- (iv) the claim replaces one or more claims as filed;
- (v) the claim is the result of the division of a claim as filed.

NOTES TO FORM PCT/ISA/220 (continued)

The following examples illustrate the manner in which amendments must be explained in the accompanying letter:

1. [Where originally there were 48 claims and after amendment of some claims there are 51]:
"Claims 1 to 29, 31, 32, 34, 35, 37 to 48 replaced by amended claims bearing the same numbers; claims 30, 33 and 36 unchanged; new claims 49 to 51 added."
2. [Where originally there were 15 claims and after amendment of all claims there are 11]:
"Claims 1 to 15 replaced by amended claims 1 to 11."
3. [Where originally there were 14 claims and the amendments consist in cancelling some claims and in adding new claims]:
"Claims 1 to 6 and 14 unchanged; claims 7 to 13 cancelled; new claims 15, 16 and 17 added." or
"Claims 7 to 13 cancelled; new claims 15, 16 and 17 added; all other claims unchanged."
4. [Where various kinds of amendments are made]:
"Claims 1-10 unchanged; claims 11 to 13, 18 and 19 cancelled; claims 14, 15 and 16 replaced by amended claim 14; claim 17 subdivided into amended claims 15, 16 and 17; new claims 20 and 21 added."

"Statement under Article 19(1)" (Rule 47.4)

The amendments may be accompanied by a statement explaining the amendments and indicating any impact that such amendments might have on the description and the drawings (which cannot be amended under Article 19(1)).

The statement will be published with the international application and the amended claims.

The statement should be brief, it should not exceed 500 words if in English or if translated into English.

It should not be confounded with and does not replace the letter indicating the differences between the claims as filed and as amended. It must be filed on a separate sheet and must be identified as such by a heading, preferably by using the words "Statement under Article 19(1)".

It should not contain any disparaging comments on the international search report or the relevance of citations contained in that report. Reference to citations, relevant to a given claim, contained in the international search report may be made only in connection with an amendment of that claim.

In what language?

The amendments must be made in the language in which the international application is published. The letter and any statement accompanying the amendments must be in the same language as the international application if that language is English or French; otherwise, it must be in English or French, at the choice of the applicant.

Consequence if a demand for international preliminary examination has already been filed?

If, at the time of filing any amendments under Article 19, a demand for international preliminary examination has already been submitted, the applicant must preferably, at the same time of filing the amendments with the International Bureau, also file a copy of such amendments with the International Preliminary Examining Authority (see Rule 62.2(a) first sentence).

Consequence with regard to translation of the international application for entry into the national phase?

The applicant's attention is drawn to the fact that, where upon entry into the national phase, a translation of the claims as amended under Article 19 may have to be furnished to the designated/elected Offices, instead of, or in addition to, the translation of the claims as filed.

For further details on the requirements of each designated/elected Office, see Volume II of the PCT Applicant's Guide.
